

8° WORKSHOP IN EMATOLOGIA TRASLAZIONALE

DELLA SOCIETÀ ITALIANA DI EMATOLOGIA SPERIMENTALE

Firenze - Auditorium CTO - A.O.U. Careggi, 22-23 giugno 2023

Applicazioni dell'Intelligenza artificiale alla stratificazione delle MDS

Matteo G Della Porta

Artificial Intelligence (AI) for precision medicine

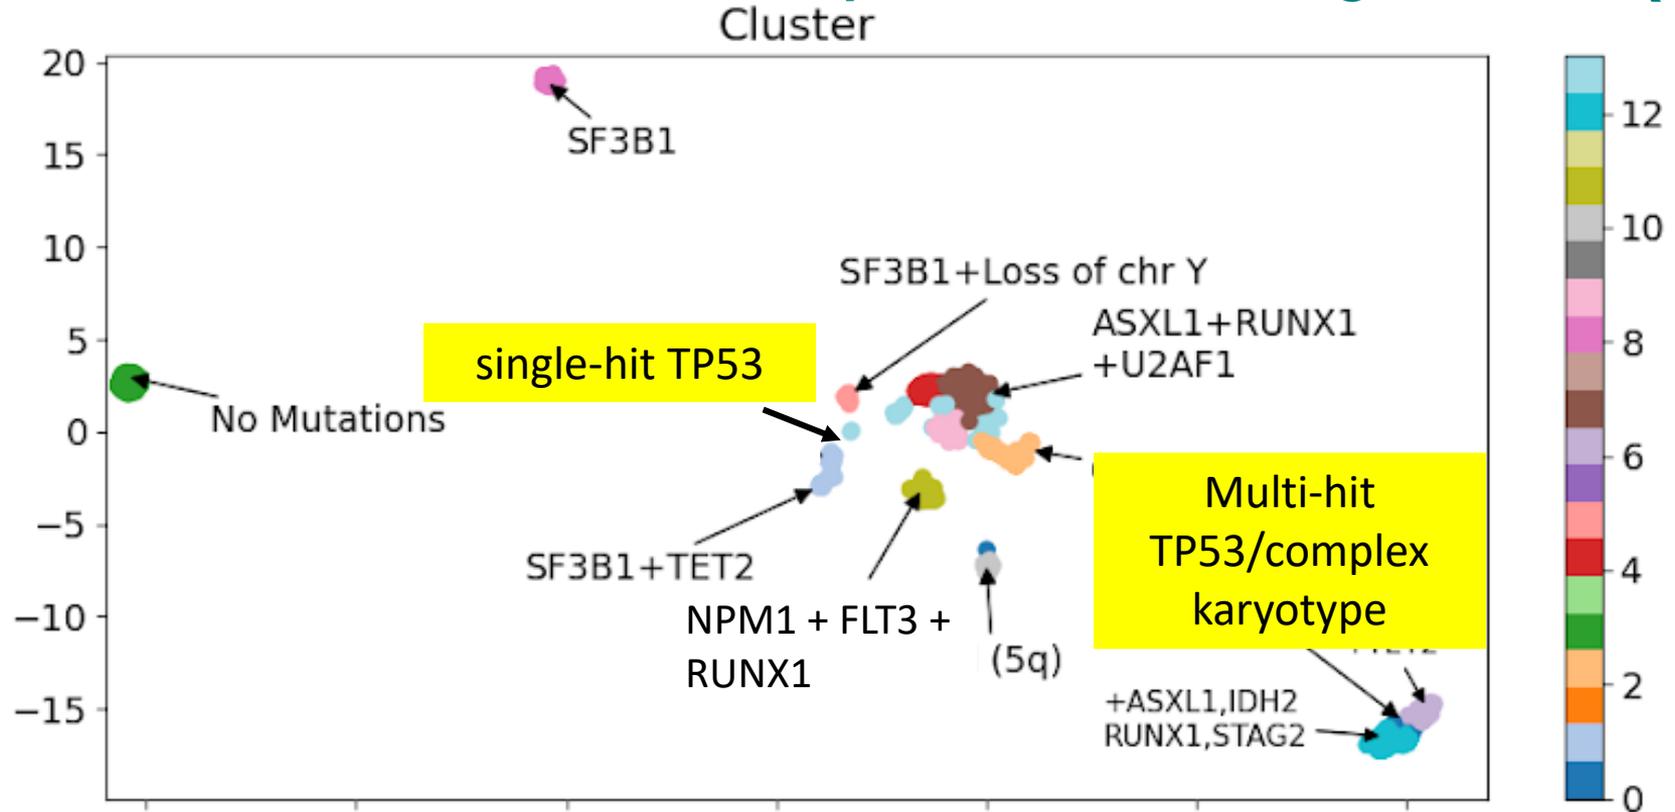

1- Machine Learning

2- Generative AI

Molecular classification of MDS by machine learning methods (AI)

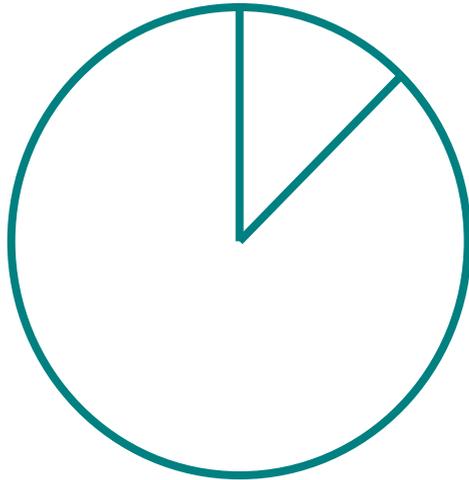

A new category of high-risk MDS is defined according to p53 dysfunction

SHAP (Shapley_Additive_Explanations) was used to explain the classification model by computing the contribution of each feature

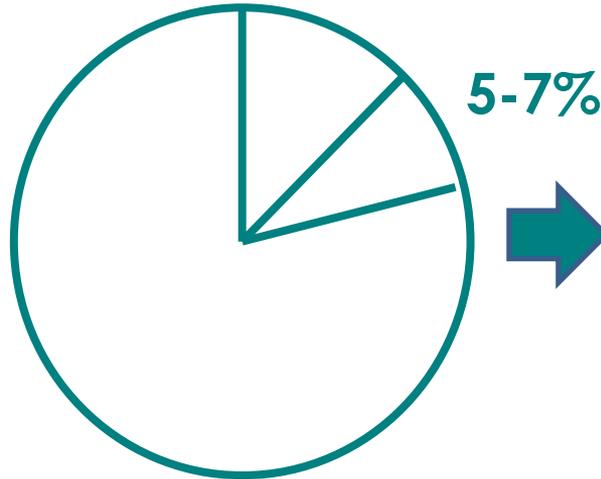

MDS with TP53-mutations

10-12%

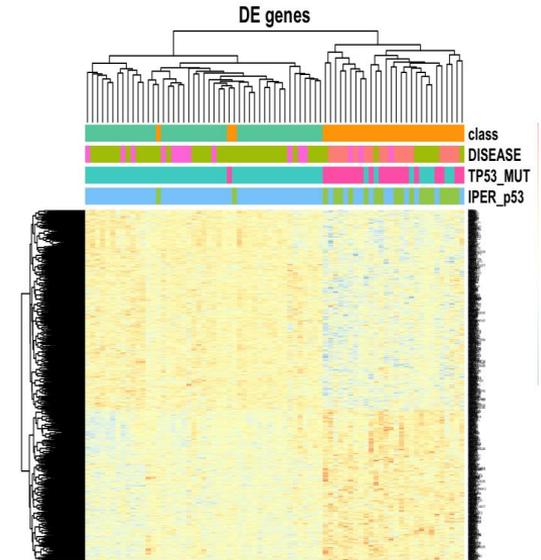

MDS with p53 dysfunction without TP53 mutations

5-7%

RNA sequencing

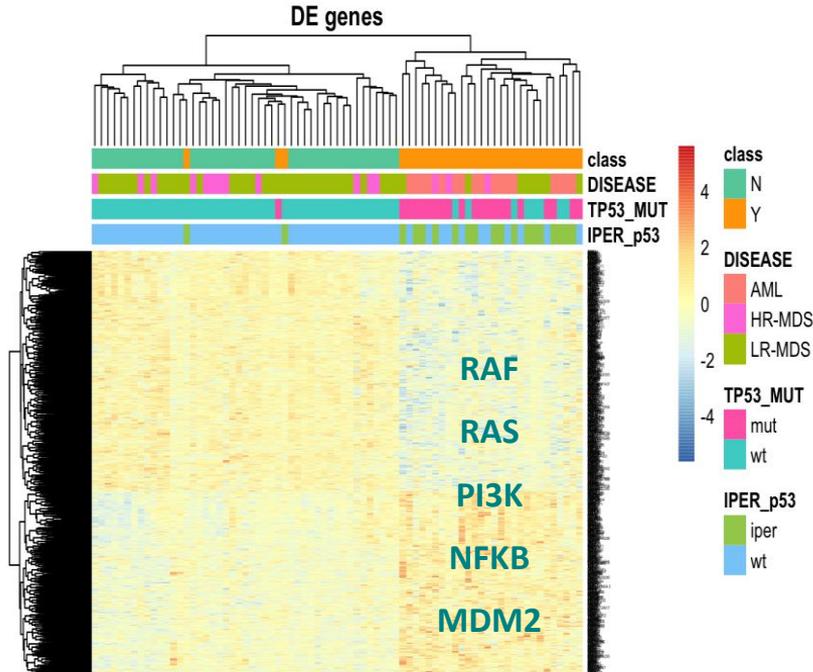

Bersanelli et al. *J Clin Oncol* 2021

Riva et al. *Blood* 2022;140:4001–4; Zampini et al, manuscript in preparation

A new category of high-risk MDS is defined according to p53 dysfunction

RNA sequencing of CD34+ progenitor cells from
236 MDS patients

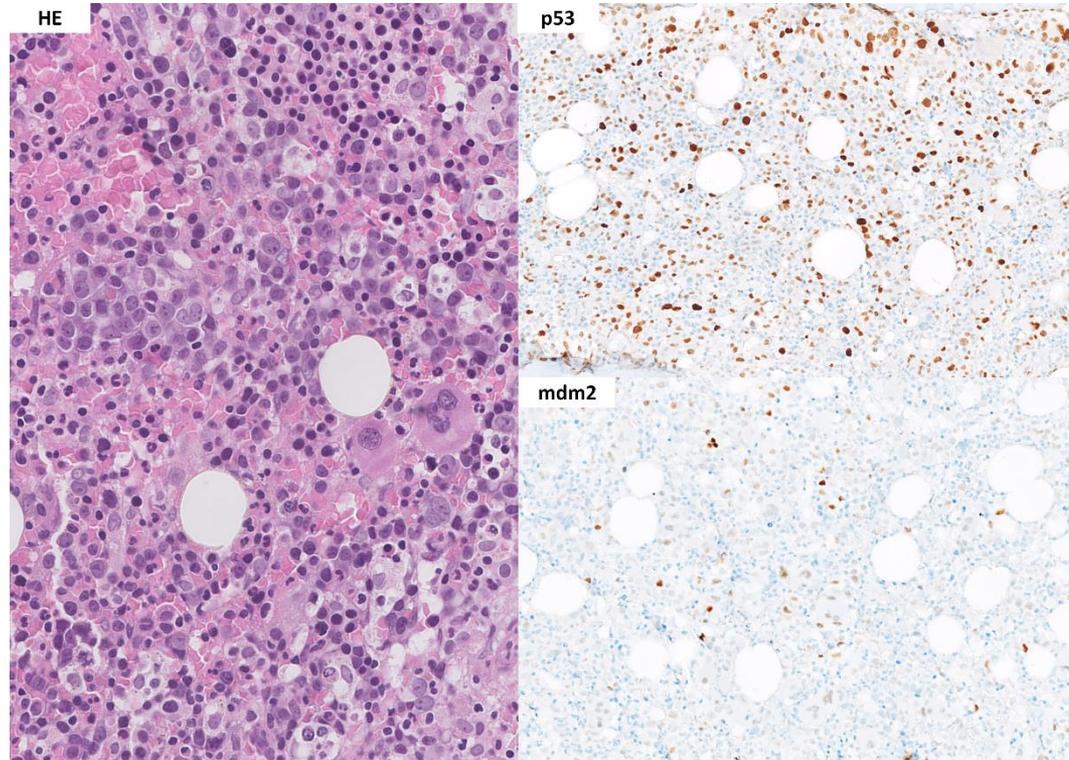

Evidence of impaired T cell and NK maturation and
function in MDS with p53 dysfunction

- » Immune checkpoint overexpression (PD-L1) at the stem cell level
- » Reduced numbers of cytotoxic T cells
- » Expansion of myeloid-derived suppressor cells (MDSCs)
- » Expansion of regulatory T cells (Tregs).
- » Impaired NK maturation and function

Sallman DA Blood (2020) 136 (24): 2812–2823

A new category of high-risk MDS is defined according to p53 dysfunction

2021 WHO guidance on ethics and governance of AI for health

We have to address three important topics, deemed as essential for a **right deployment of AI in hematology**:

- **Transparency of models.** We have to provide a good understanding of the models (interpretability and explainability)
- **Reliability of models.** The main vulnerabilities of AI models are related to lack of generalizability. Therefore, extensive, independent validation of generated AI-models is required.
- **Protection of data and data sharing.** Innovative technologies such as federated learning procedures for data collection and analysis (without moving sensitive medical data from their original locations) are required to facilitate clinical implementability of AI solutions

Artificial Intelligenza (AI) for precision medicine

1- Machine Learning

2- Generative AI

Generation of Synthetic Data to accelerate Research & Development in MDS

- In MDS the first evidence of recurrent somatic mutations in splicing-related genes was published in 2011 and only 10 years later large patient populations ($n > 2,000$) with comprehensive clinical and molecular information were available to test clinical significance and implementability of genomic screening
- The development of innovative data-driven digital health products and services, in fact, is currently slowed due to limited access to / availability of data. Additional challenges in health data include harmonization problems and data privacy (GDPR)
- **Synthetic data** are artificial data generated by an algorithm trained to learn all the essential characteristics of a real dataset. The new data are neither a copy nor a representation of the real data. Since they are not real data, they are not regulated by particular limitations so they can be easily accessed and shared.

Generation of synthetic data to accelerate Research & Development in MDS

- Synthetic data can be generated by using neural networks (Generative Adversarial Networks, GAN).

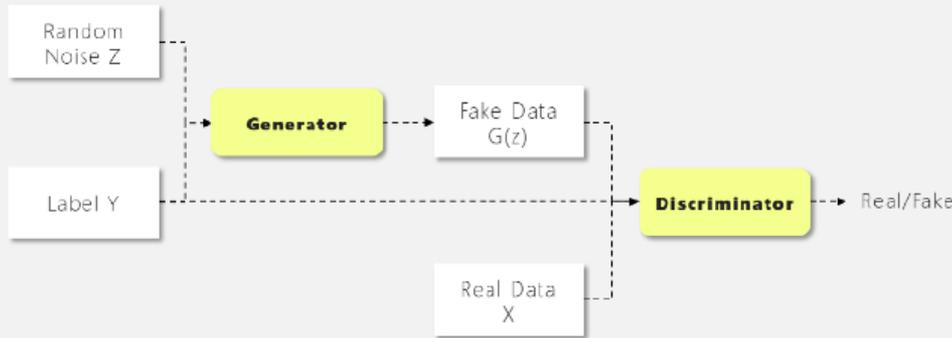

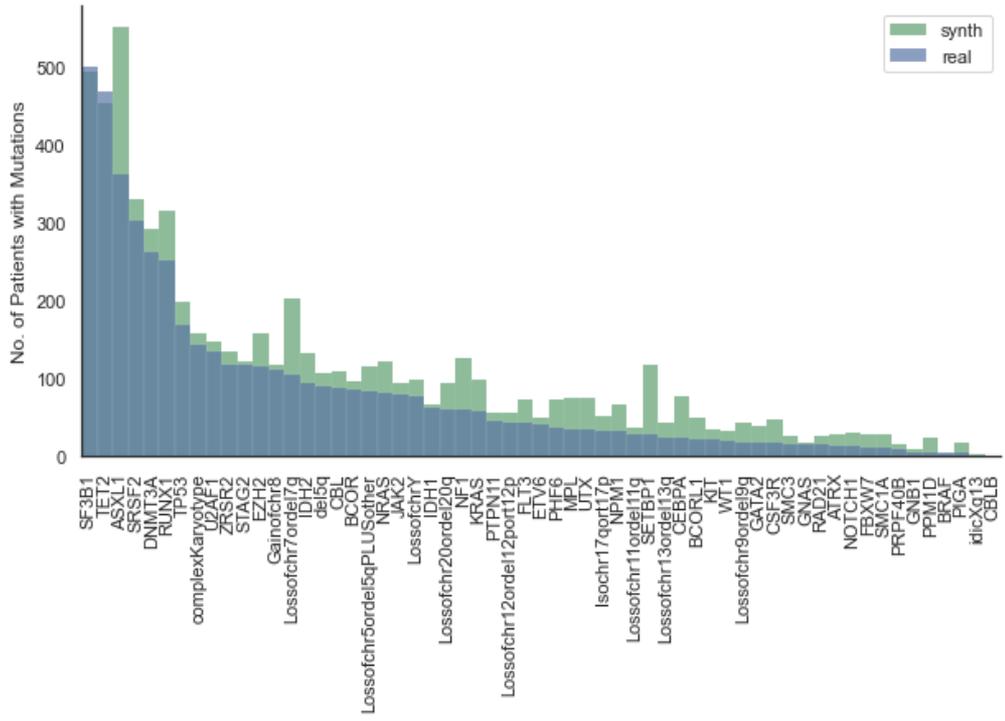

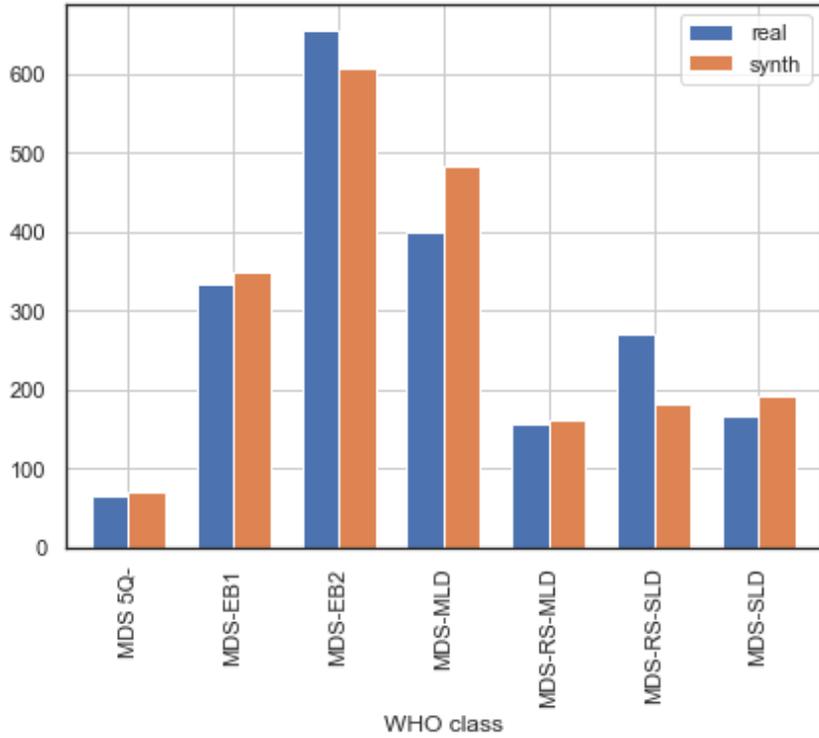

Figure 2 Conditional Generative Adversarial Networks architecture

Possible applications

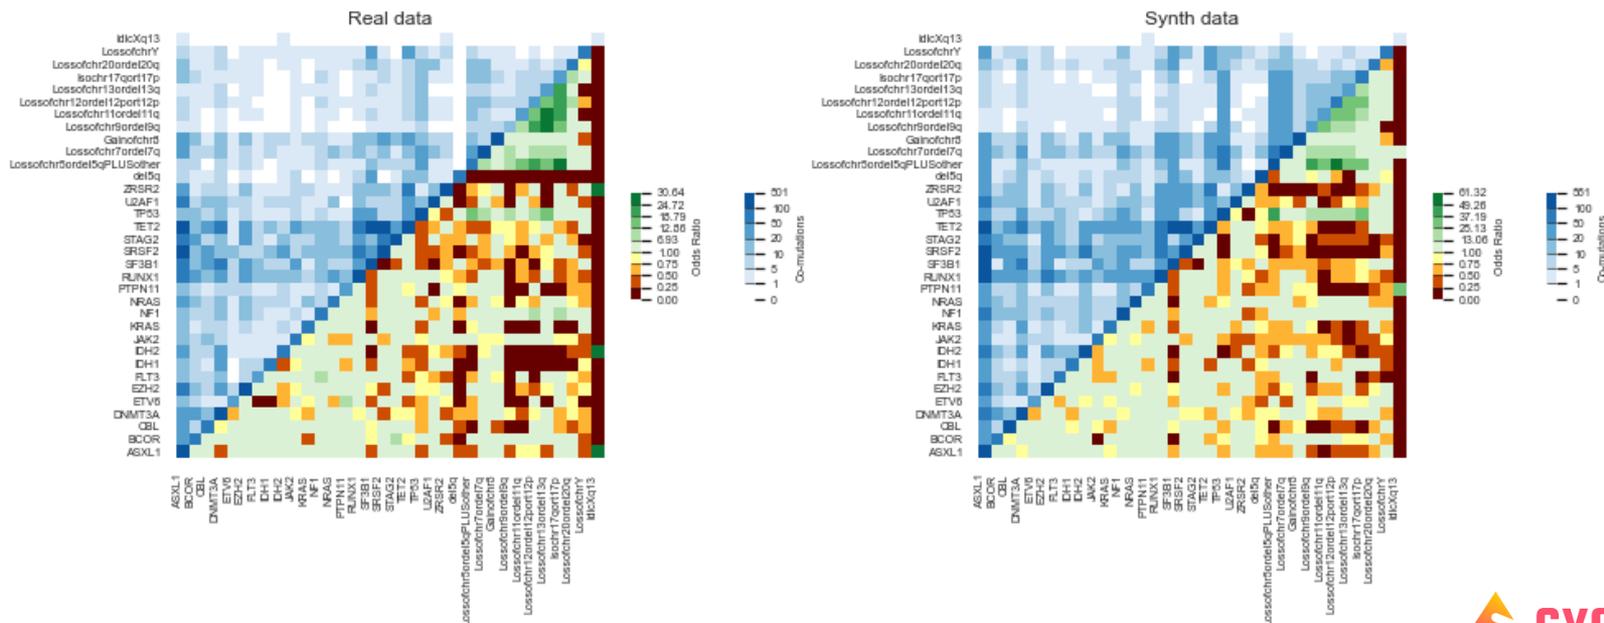

- Data sharing (GDPR)
- Classes balance and resolution of missing information
- Data augmentation for learning/validation purpose
- Generation of new evidence

Synthetic vs. Real Data: comparison of clinical and molecular features

Synthetic vs. Real Data: pairwise association among genes and cytogenetic abnormalities

Pairwise associations among genes and cytogenetic abnormalities

Synthetic vs. Real Data: survival

COX models (overall survival)

Probability of OS stratified by IPSS-R

Real data:

Global Concordance: 0.779; Std.err:0.013

Partial Concordance of risk components:

	Clinical	CNA	Demographics	Genetics
concordant	0.711	0.569	0.630	0.782
std(c-d)	0.013	0.011	0.013	0.013

Synthetic data:

Global Concordance: 0.822; Std.err:0.013

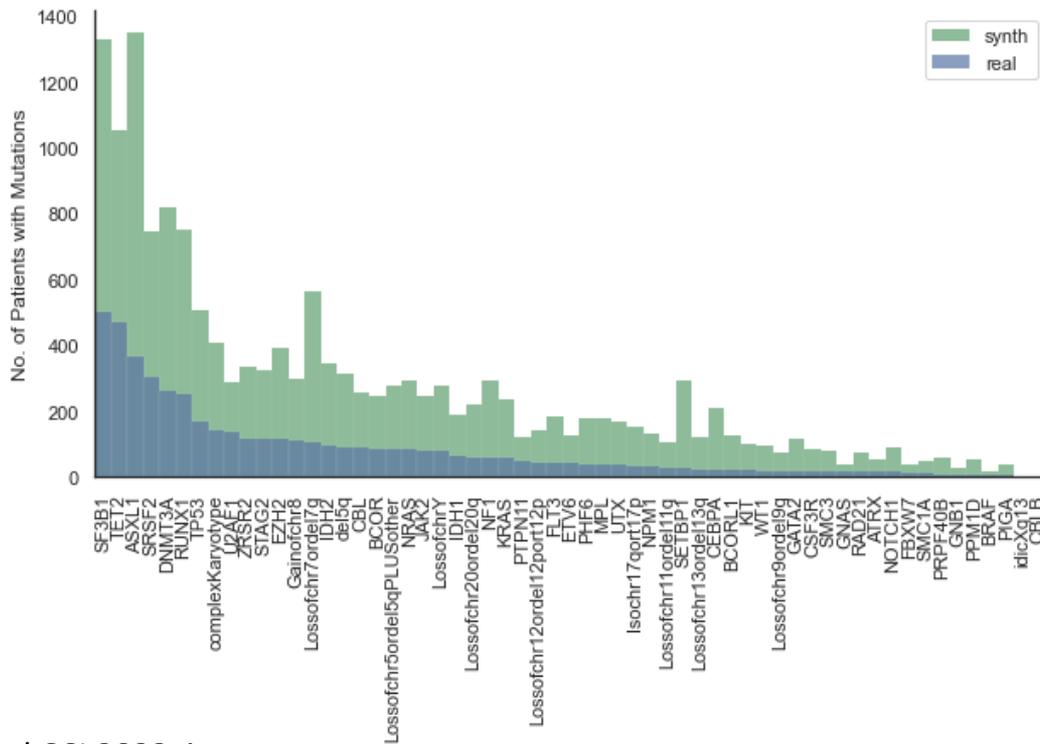

Partial Concordance of risk components:

	Clinical	CNA	Demographics	Genetics
concordant	0.732	0.536	0.646	0.746
std(c-d)	0.013	0.011	0.013	0.013

Synthetic vs. Real Data: data augmentation

Data augmentation: from 2043 to 5000 patients

Performance of Synthetic Data

DEMOGRAPHIC, CLINICAL AND SURVIVAL DATA

92.1 %

SYNTHETIC CLINICAL FITNESS

Evaluated with distribution plot,
Principal Component Analysis and
correlation matrices.

GENOMIC DATA

90.2 %

SYNTHETIC GENOMIC FITNESS

Evaluated with mutation frequencies
and pairwise association.

ALL DATA

70.6 %

PRIVACY PRESERVABILITY

Evaluated considering the possibility of
tracing real data from synthetic ones.

Generation of Synthetic Data to accelerate translational research in Hematology
