

Does conditioning intensity matter?

the NO position

16-Giugno-2023

Francesco Saraceni

Clinica di Ematologia, Azienda Ospedaliero-Universitaria delle Marche

No conflict of interest to declare

The ideal transplant platform

What can we expect from a modern transplant platform (conditioning regimen + GVHD prophylaxis?)

- Engraftment (do we always need myeloablation?)
- Low extrahematological toxicity
- High anti-leukemia efficacy to let time for GVL effect to take over
- Low rates of aGVHD, no grade 3-4 aGVHD
- No or mild cGVHD

The dilemma of dose intensity – the conditioning intensity axiom

The conditioning intensity axiom:

- Reduced intensity has the rationale of reduced non-relapse mortality (NRM)
- Increased intensity results in reduced relapse (REL)
- NRM and REL are inversely proportional
- Survival depends on the sum of the competing factors NRM + REL

The survival equation:

$$\text{OS} = 1 - (\text{NRM} + \text{REL})$$

$$\text{NRM} * \text{REL} = k$$

The dilemma of dose intensity – a paradigmatic example

Let's solve the equation:

TBI 15.75 Gy

$$\begin{aligned} \text{OS} &= 1 - (\text{NRM} + \text{REL}) \\ &= 1 - (0.4 + 0.1) \\ &= 1 - 0.5 \\ &= 0.5 \end{aligned}$$

TBI 12 Gy

$$\begin{aligned} \text{OS} &= 1 - (\text{NRM} + \text{REL}) \\ &= 1 - (0.1 + 0.4) \\ &= 1 - 0.5 \\ &= 0.5 \end{aligned}$$

Different intensity: similar survival

The evolving concept of transplant eligibility

Relative Proportion of Allogeneic HCTs for Malignant Diseases* in the US by Recipient Age

Higher flexibility in transplant eligibility

*includes Acute myelogenous leukemia, Acute lymphoblastic leukemia, Myelodysplastic syndromes/Myeloproliferative neoplasms, Non-Hodgkin lymphoma, Hodgkin lymphoma 32

Older/unfit patients: intensity = toxicity

Comorbidity Score in Allogeneic HCTs in the US by HCT CI Group, Adults

We are forced to de-escalate intensity in this population

Can we prove the axiom wrong?

What do we need intensity for?

1. To engraft stem cells: no need for high intensity in AML
2. To eradicate residual disease: does intensity really matter?

Let's get rid of dose intensity!

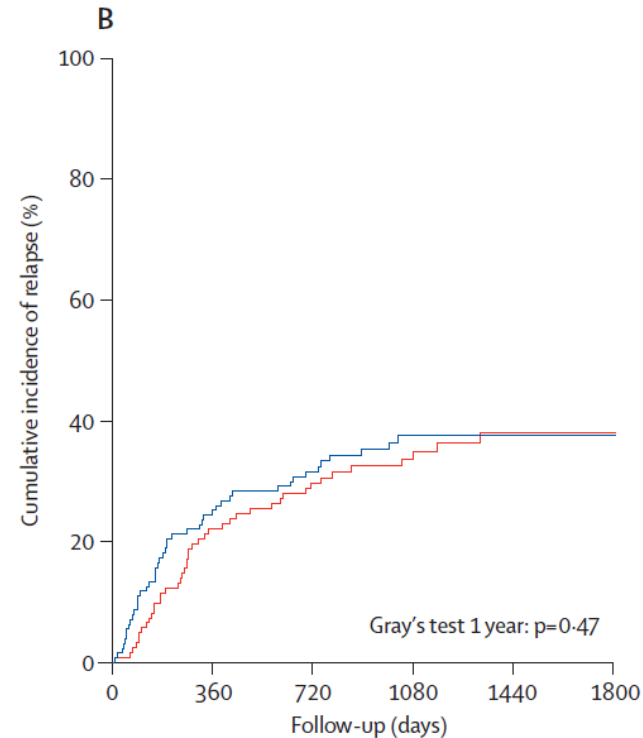

Let's prove the axiom wrong - we need randomized studies

Let's get rid of dose intensity – 1

GITMO phase III, randomized trial. Pivotal study
Bu-Cy vs Bu-FLU (2 vs 1 alkylator)
AML 40-65y, HLA matched related or UD ($\geq 9/10$)

Primary endpoint: 1 year NRM: met
NRM: 19% (BuCy) vs 10% (BuFlu)
Organ failure: 7% (BuCy) vs less than 1% (BuFlu)
No difference in survival

Reduced NRM, however REL not increased

Let's get rid of dose intensity - 2

RICMAC EBMT trial, Phase III, randomized
RIC vs MAC (Bu2-Flu vs Bu-Cy)
MDS + secondary AML
HLA matched related or UD ($\geq 9/10$)

RIC: trend for better OS compared to MAC (in MDS)

Yes, we can! The axiom was wrong:
Reduced NRM does not necessary lead to increased REL

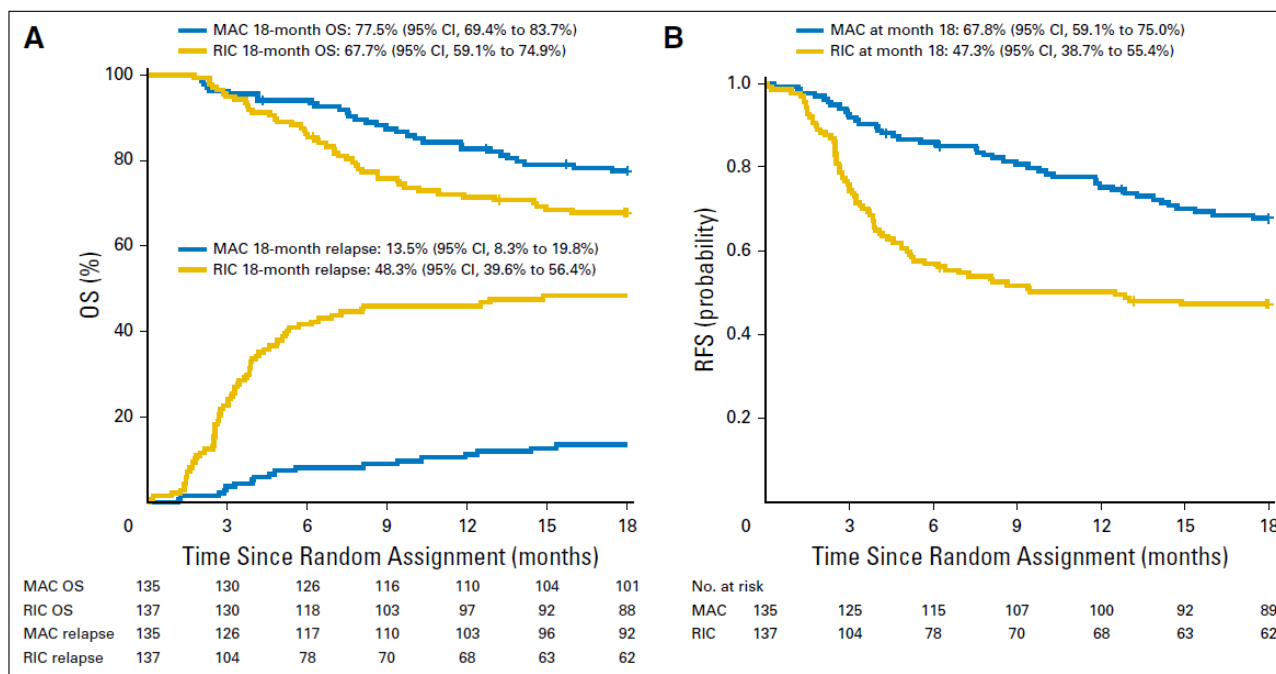

De-escalating dose intensity for all patients? RIC for everybody!

US-CTN 0901 study, Phase III randomized trial, MAC vs RIC

271 patients with AML or MDS

Age 18-65, HCT-CI max 4

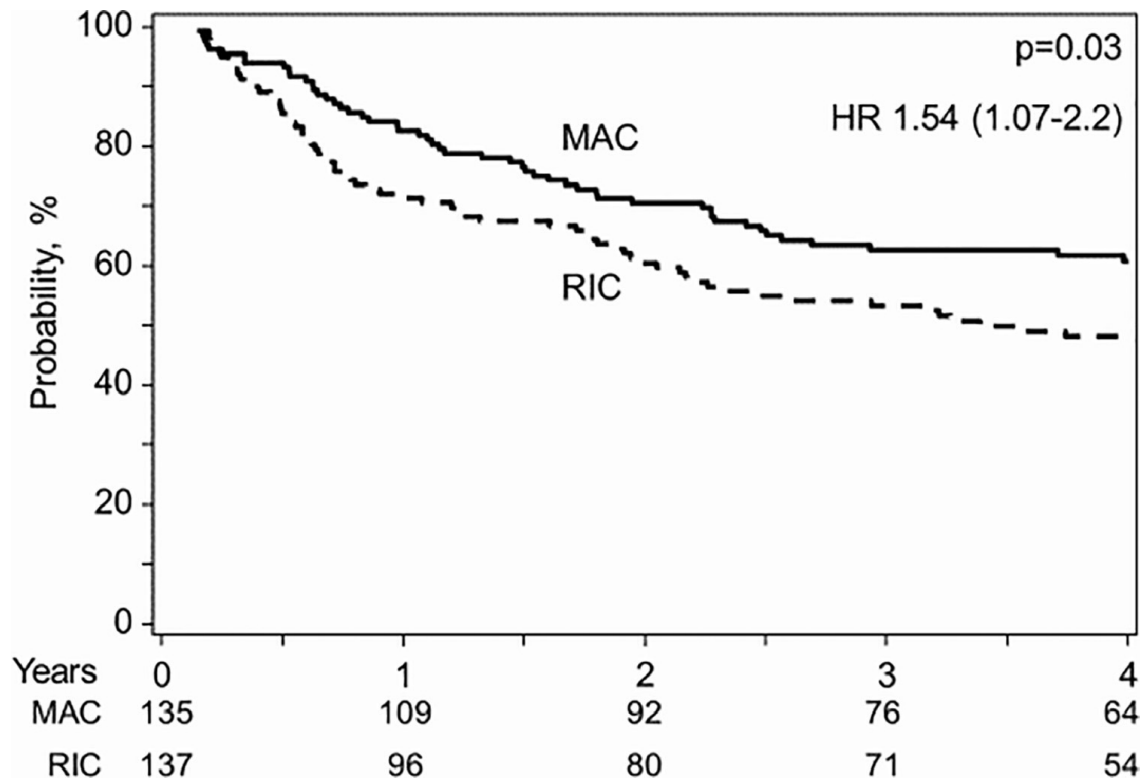

MAC: Bu/Cy or Cy/TBI; RIC: Bu2/Flu or Flu/Mel

Increased relapse in AML (not in MDS): 48% (RIC) vs 14% (MAC)

Increased LFS MAC vs RIC

De-escalating dose intensity for all patients? NO, we can't

MAC vs RIC: improved survival (AML only)

Was the axiom right, after all?

Don't even think about RIC in young, fit AML patients!

Can we improve over conventional RIC regimens? Treosulfan

Randomized, phase III Trial (MC-FludT.14/L Trial), Bu-Flu vs Treo-Flu
18–70 years, AML CR or MDS

HLA-matched related or UD ($\geq 9/10$)

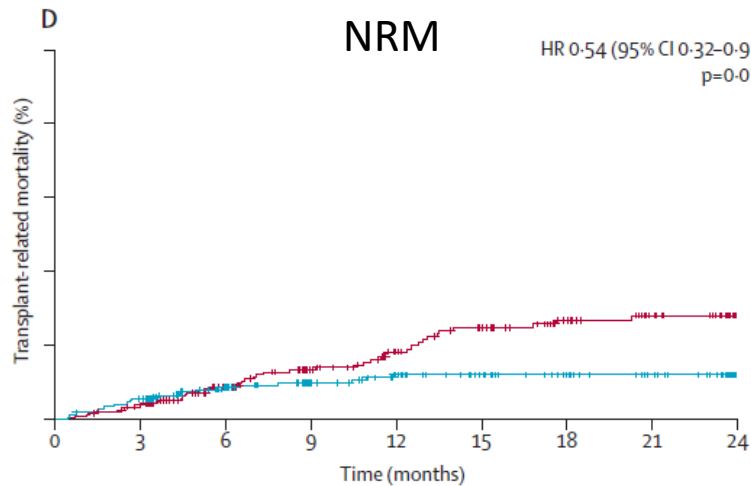

Key inclusion criteria: considered ineligible for Myeloablative regimen based on:

- **Age ≥ 50 y**

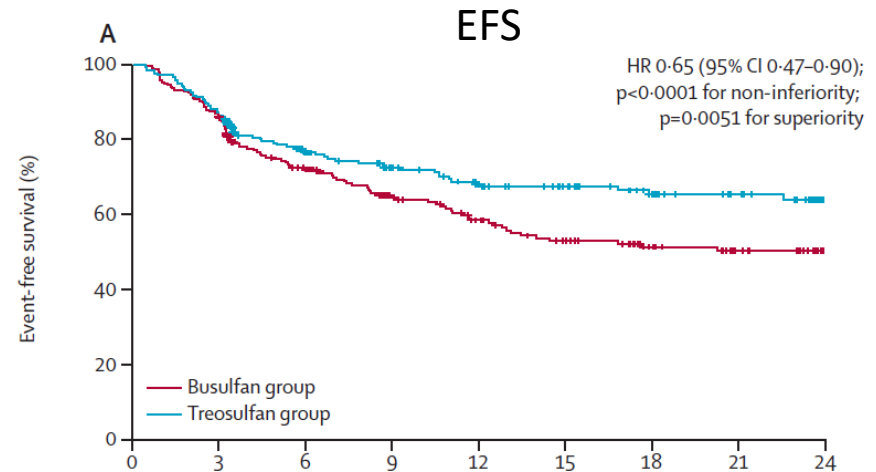

And/or **HCT-CI >2**

Treo 10 g/m² (3 days) vs Bu 3,2 mg/kg (2 days)

+ Fludarabine 30 mg/m² (5 days)

NRM gap widens beyond 6 months

Primary endpoint: met. Improved EFS

Can we improve over conventional RIC regimens? Treosulfan

Improved OS

	Busulfan group		Treosulfan group		HR	HR (95% CI)	p

0.1 0.5 11.3 5 10
Favours treosulfan Favours busulfan

After all, is conditioning intensity the right focus?

Conditioning intensity is the result of the combination of:

1. The inherent pharmacodynamic properties of the single conditioning agents
2. The resultant toxicity to that given patient

(patient-related variables as, Age/comorbidities/dynamic fitness
previous chemotherapy, alkylator dosing in obese pts, drug-drug interactions etc.)

+ GVHD prophylaxis should be taken into account (ptCY vs ATG/MTX/CSA vs T-cell depleted HSCT)

The ptCY case:

i.e.

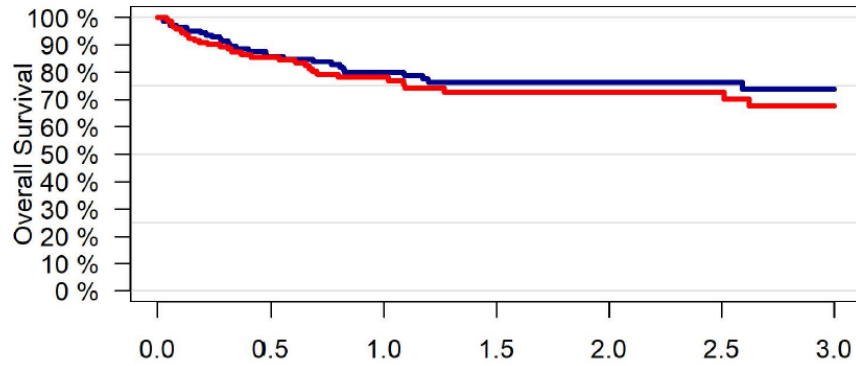

Myeloablative TBI-based conditioning + ptCY

Double alkylator conditioning + ptCY

High toxicity is expected

Treosulfan as an alternative to double alkylator in ptCY haplo for AML

d) OS

2-years OS	
Treo	76%
TBF	73%
<i>P</i>	0.53

No. risk	0.5	1.0	1.5	2.0	2.5	3.0
Treo: 142	76	37	26			
TBF: 142	64	41	21			

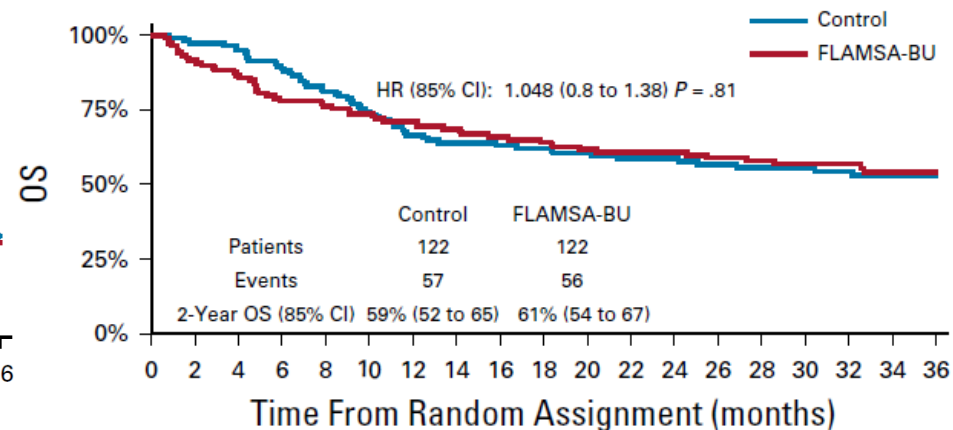

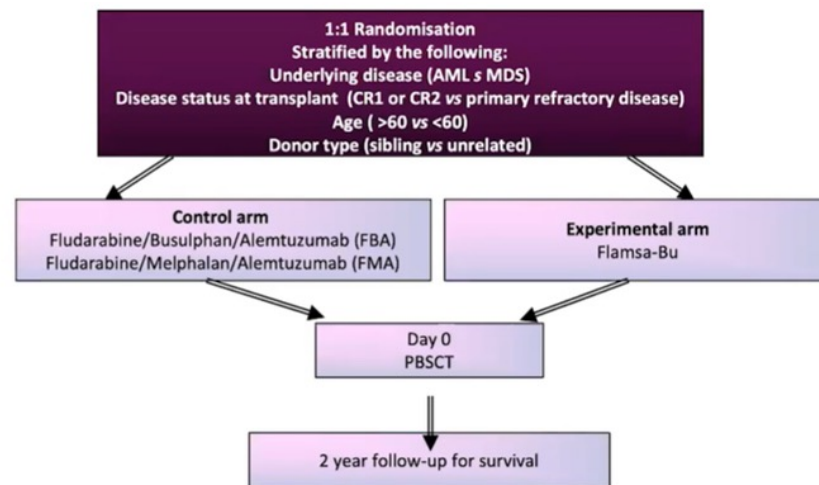

RIC subgroup

2y	NRM	RI
Treo	13%	20%
TBF	24%	13%
	P=0.2	P=0.7

2y	LFS	OS
Treo	67%	77%
TBF	64%	68%
	P=0.6	P=0.3

Don't forget we are in 2023, we have MRD! The FIGARO trial

Phase III, randomized trial
 244 AML or MDS patients
 Not eligible to MAC
 RIC vs intensified sequential conditioning
 MRD prospectively evaluated by MFC

Intensified regimen did not improve outcome
 Relapse rate 25-30% as expected, different from US-CTN 0901 trial

FIGARO UK trial - MRD

Detrimental effect of pre-transplant MRD (0,2% cutoff) on cumulative incidence of relapse

No benefit of regimen intensification in positive MRD

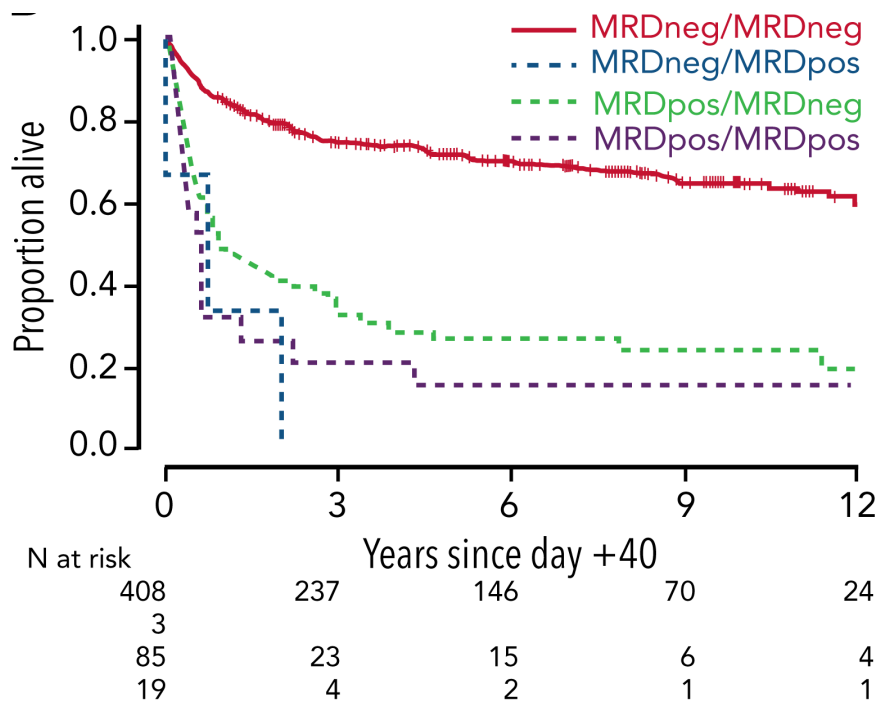

RIC MRDpos: relapse 40% (2y), survival 50% (2y)

RIC - HSCT is not futile in an elderly/unfit patient with positive MRD

Seattle – MAC vs NMA/RIC, MRD pre/post HSCT

810 AML CR1 or CR2; MAC vs non-MAC (RIC/NMA)

MRD by flow pre/post HSCT (peritransplant MRD)

MAC

NMA/RIC

Look at the green curve: RIC better than MAC in MRDpos (?)

RIC in MRDpos: 3y OS about 50%

Conclusion

- Crude conditioning intensity is not the best focus
- To design a patient-oriented HSCT platform (not just conditioning) is probably a better target
(Donor choice, GVHD prophylaxis, AML therapy before HSCT, post-HSCT interventions significantly interact with conditioning intensity for NRM)
- To transplant an high risk >65y AML patient remains a main challenge
- Reduced intensity regimens represent a valid choice in patients not eligible for MAC
- RIC regimen can deliver good long term outcome even in high risk pts (i.e. MRDpos)
- Let's base our practice on good quality evidence, we have (few) data from randomized trials

Strike firmly but gently, transplant is not all about conditioning!

Grazie
