Stem cells, cancer, and cancer stem cells

Tannishtha Reya*§||, Sean J. Morrison†||, Michael F. Clarke‡ & Irving L. Weissman*

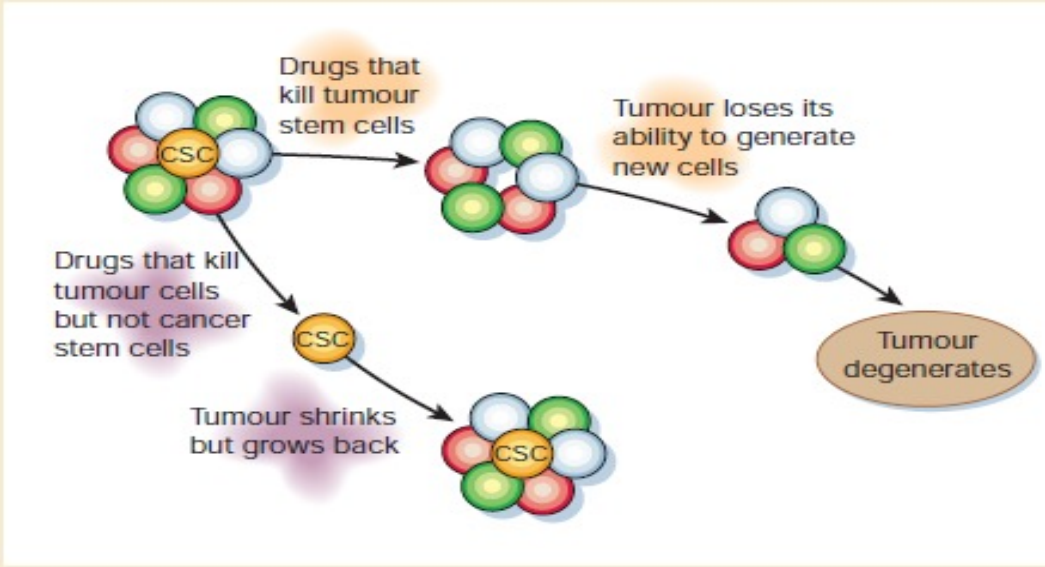

Figure 5 Conventional therapies may shrink tumours by killing mainly cells with limited proliferative potential. If the putative cancer stem cells are less sensitive to these therapies, then they will remain viable after therapy and re-establish the tumour. By contrast, if therapies can be targeted against cancer stem cells, then they might more effectively kill the cancer stem cells, rendering the tumours unable to maintain themselves or grow. Thus, even if cancer stem cell-directed therapies do not shrink tumours initially, they may eventually lead to cures.

unit in 250,000 cells. We fractionated AML cells on the basis of cell-surface-marker expression and found that the leukaemia-initiating cells that could engraft SCID mice to produce large numbers of colony-forming progenitors were $CD34^+CD38^-$; however, the $CD34^+CD38^+$ and $CD34^-$ fractions contained no cells with these properties. This *in vivo* model replicates many aspects of human AML and defines a new leukaemia-initiating cell which is less mature than colony-forming cells.

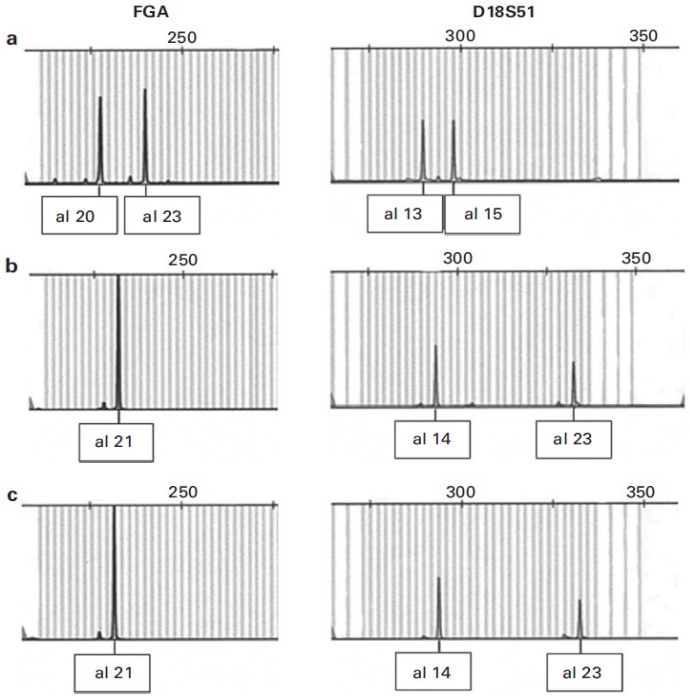
Donor cell-derived leukemia after cord blood transplantation and a review of the literature: differences between cord blood and BM as the transplant source

H Shiozaki, K Yoshinaga, T Kondo, Y Imai, M Shiseki, N Mori, M Teramura and T Motoji

Bone Marrow Transplantation (2014) 102 – 109



Several mechanisms for the development of DCL after CBT have been proposed. One possibility is that the donor cord blood itself may contain leukemic clones at the time of transplantation. Mori *et al.*[69] reported the presence of the *TEL–AML1* fusion gene in 6 of 567 cases of unselected umbilical cord blood cells and the *AML1–ETO* fusion gene in 1 of 496 cases. The presence of the *AML1–ETO* fusion gene sequence was also reported in the neonatal blood spots of children who developed AML later.[70] A transferred leukemic clone would be 'the first hit' of leukemogenesis after CBT, and then additional hits could lead to leukemia. From the data showing a shorter period for the occurrence of DCL following CBT and the high frequency of monosomy 7 in DCL, it is natural enough to consider that an umbilical leukemia clone could have been transplanted into the recipient, which could cause DCL.

Another possibility that may explain the development of DCL after CBT is that even if the transplanted cord blood cells are intact, the environment of the recipients may permit the occurrence of leukemia. This mechanism might be also applicable to DCL following BMT. The microenvironments in recipients, including stem cell niches or stromal cells, have been reported to be changed by irradiation or chemical agents,[71] which may lead to impaired immune surveillance or dysregulation of cytokines or homeostasis for hematopoiesis. Indeed, deficiencies in antigen-specific cellular immunity within the first 100 days after CBT have been demonstrated.[72] Further, a high proliferation of cord blood cells may be sufficient for inducing replication errors or mutations in the DNA.[73]

BLOOD, 2 APRIL 2009 • VOLUME 113, NUMBER 14

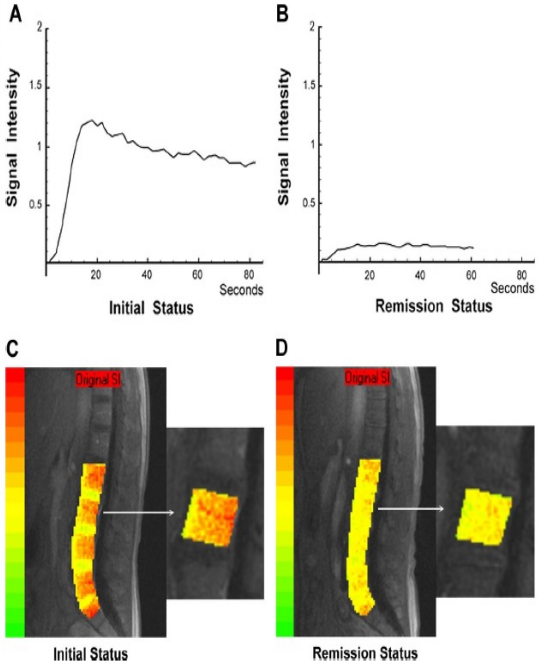

Figure 1. The time-intensity curves derived from DCE-MRI and color-coded angiogenesis maps of vertebral bone marrow in a 54-year-old female patient with de novo AML are shown. She achieved complete remission after induction chemotherapy. Her remission duration until the end of August 2007 was 1002 days. The time-intensity curve (A) and color-coded angiogenesis map (C) at initial diagnosis are shown; those in complete remission are shown (B,D), respectively.

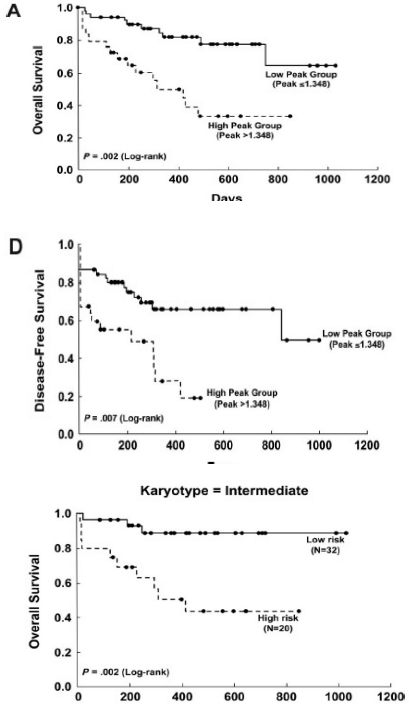

High Acute Myeloid Leukemia derived VEGFA levels are associated with a specific vascular morphology in the leukemic bone marrow

[1]Nuffield Department of Obstetrics and Gynaecology, The University of Oxford, John Radcliffe Hospital, Oxford, OX3 9DU, United Kingdom; [2]Nuffield Department of Clinical Laboratory Sciences, The University of Oxford, John Radcliffe Hospital, Oxford, OX3 9DU, United Kingdom; [3]Molecular Angiogenesis Laboratory, Cancer Research UK, Weatherall Institute of Molecular Medicine, The University of Oxford, John Radcliffe Hospital, Oxford, OX3 9DU, United Kingdom; [4]Institute for Biomedical Research, Birmingham University Medical School, Edgbaston, Birmingham B15 2TT, United Kingdom

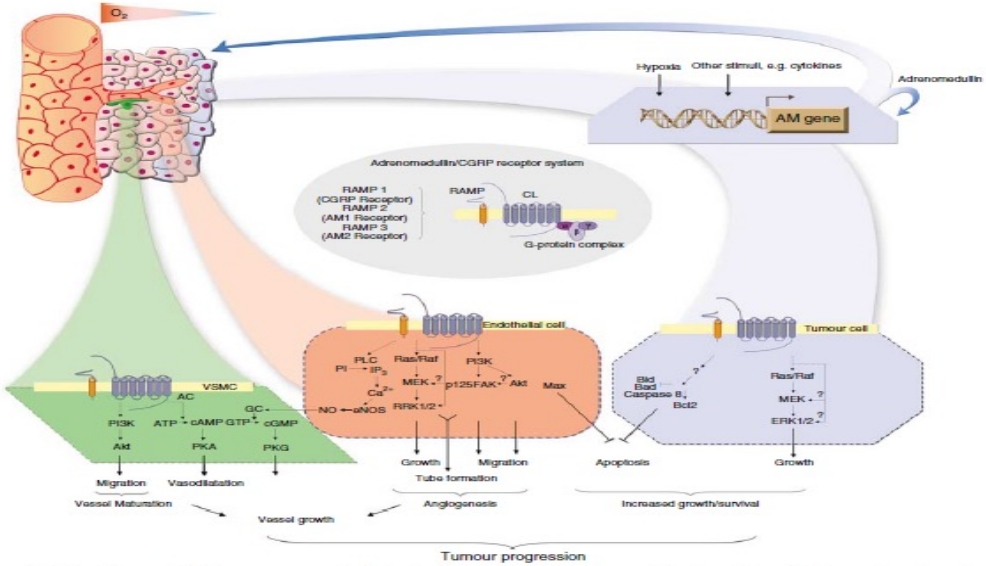

Figure 1 Role of adrenomedullin in tumour progression. The role of hypoxia and inflammatory cytokines in regulation of AM expression and secretion by tumour cells *in vivo* has been suggested. Adrenomedullin promotes formation of xenografted tumours by stimulation of autocrine growth and survival of tumour cells, and through paracrine effects on surrounding vessels. Possible intracellular signalling mechanisms underlying effects of AM in tumour microenvironment (in endothelial, vascular smooth muscle (VSMC) and tumour cells) suggest its potential role in tumorigenesis, resistance to chemotherapy and tumour progression. Based on McLatchie *et al* (1998), Shichiri *et al* (1999), Hinson *et al* (2000), Oehler *et al* (2001), Martinez *et al* (2002), Poyner *et al* (2002), Kim *et al* (2003) and Iwase *et al* (2005). AC = adenylate cyclase, GC = guanylate cyclase; PKA = protein kinase A, PKG = protein kinase G, PLC = phospholipase C, MEK = mitogen-activated protein kinase kinase; ERK = extracellular signal-regulated kinase (also termed MAPK).

Adrenomedullin in the growth modulation and differentiation of acute myeloid leukemia cells

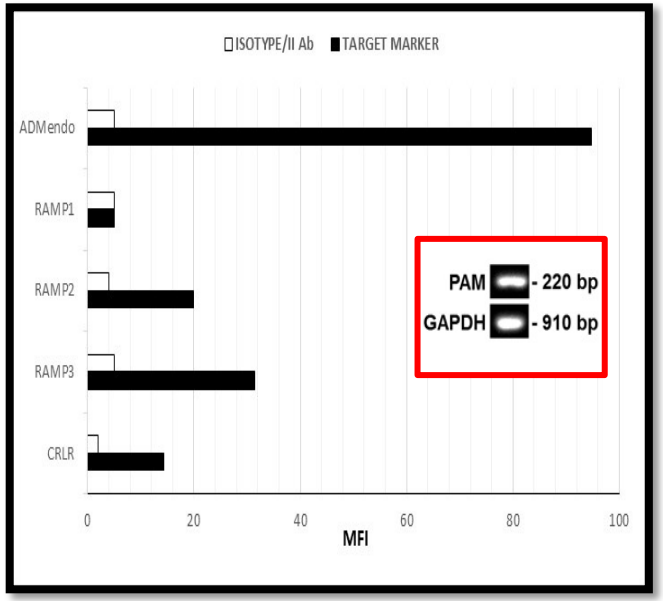

Figure 2. (A) The immunophenotypic analysis was performed by FCM to detect the expression of endogenous ADM (ADM_{endo}), ADM receptors (RAMP1/2/3, CRLR) using specific primary antibodies and Alexa Fluor 488- and PE-conjugated secondary antibody. In parallel, secondary antibody-matched controls were used as reference. For each marker, the percentage (%) ± SD of positive cells (grey peak) was detected by the substraction statistical tool of Summit 4.3 software using as reference II Ab-matched control (black peak). (B) Analysis by RT-PCR of PAM gene in HL60 cells cultured at basal conditions. In parallel, the expression of *GAPDH* housekeeping gene was considered. The amplification products were electrophoresed on 2% agarose gel and stained by GelRed™.

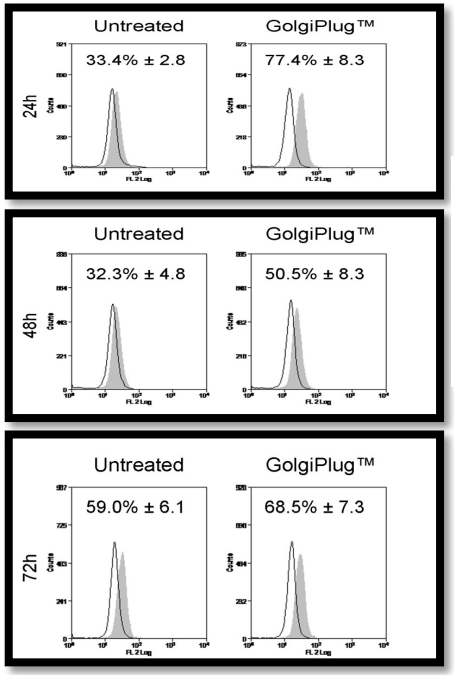

Figure 3. ADM secretion in HL60 cells was demonstrated using protein transport inhibition. Cells were cultured for 12, 36 and 60 h in proliferation medium before incubation for 12 h with Brefeldin A/GolgiPlug™. Thus, the samples were collected at 24, 48 and 72 h from plating and analyzed by intracellular ADM staining followed by flow cytometric analysis. In this analysis, cultures untreated with GolgiPlug™ were used as positive control of ADM secretion. The acquired data were expressed as a percentage (%) ± SD of ADM positive cells (grey filled peak) compared to II Ab-matched control (black profile).

Some Reasons to Deeper Investigate the Vascular Niche in Acute Myeloid Leukemia

Gottardi M[1*], Conconi MT[2], Gherlinzoni F[1] and Di Liddo R[2]

[1]Hematology, Ospedale Ca' Foncello, Italy

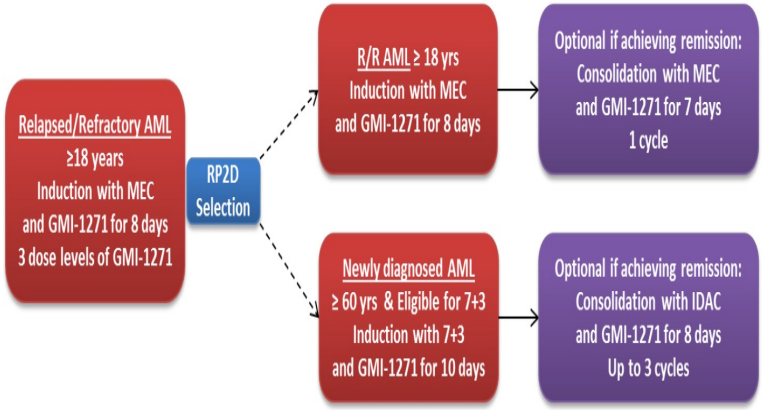
[2]Department of Pharmaceutical and Pharmacological Sciences, University of Padova, Italy

microenvironmental influences. HSC niche is generally divided into two compartments: a hypoxic endosteal bone marrow niche, that is developed within cancellous/trabecular bone and a vascular niche characterized by higher oxygen tension. The former is believed to maintain the HSCs in a quiescent state, especially during bone marrow repair. Hypoxia, that has been demonstrated to preserve the stemness of HSCs through the stabilization of the master transcriptional regulator of hypoxia response (HIF-1α), is a prominent feature of BM microenvironment in different hematological malignancies, such as leukemia [6]. A growing body of evidence suggests that HIF-1α promotes the quiescence of leukemic cells residing in the endosteal niches, thus contributing to the persistence of a minimal residual disease [7]. Finally, it has been demonstrated that hypoxia is able to activate a stemness genomic signature in cancer cells through the up-regulation of some genes such us *OCT-3/4*, *NANOG*, and *SOX2* [8], two of which were used by Takahashi and Yamanaka to generate induced Pluripotent Stem cells (iPS) from fibroblasts [9]. Based on numerous studies reporting the functional role of the endosteal niche as L-IC supportive microenvironment, therapies interfering with the endosteal localization of blasts have been proposed as a valid strategy for AML treatment. Unlike the endosteal niche, the vascular

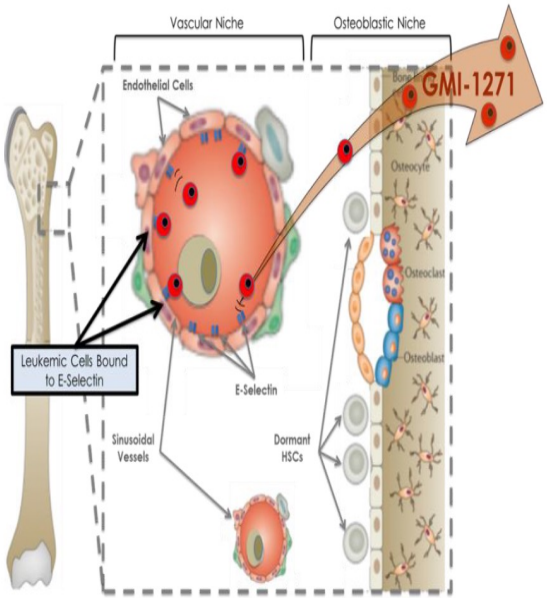
In conclusion, the vascular niche can behave as an L-IC supportive microenvironment and consequently may represent an attractive target for selective therapies. To our opinion this is the main, among other, reason to deeper investigate the vascular niche in AML.

GMI-1271 improves efficacy and safety of chemotherapy in R/R and newly diagnosed older patients with AML: results of a Phase 1/2 study

Daniel J. DeAngelo, Brian A. Jonas, Jane L. Liesveld, Dale L. Bixby, Anjali S. Advani, Paula Marlton, Michael E. O'Dwyer, John L. Magnani, Helen M. Thackray, Pamela S. Becker



GMI-1271, an E-selectin Antagonist, Disrupts the Relationship Between Tumor Cells and Bone Marrow Microenvironment



E-selectin –

- Constitutively expressed in the bone marrow microvasculature
- Binds to the E-selectin ligand on AML cells
- Promotes cell-adhesion-mediated drug resistance (CAMDR) of leukemic cell

GMI-1271, an E-selectin antagonist –

- Inhibits activation of cancer survival pathways (e.g. NF-KB), disrupting CAMDR within bone marrow micro-environment
- Protects normal HSCs by enhancing quiescence and ability for self-renewal
- Reduces chemotherapy-associated mucositis

Acute myeloid leukemia

The neuropeptide receptor calcitonin receptor-like (CALCRL) is a potential therapeutic target in acute myeloid leukemia

INHIBITORS OF ADRENOMEDULLIN FOR THE TREATMENT OF ACUTE MYELOID LEUKEMIA BY ERADICATING LEUKEMIC STEM CELLS
Application WO-2021099600-A1
Abstract
The emergence of cells with drug resistant and/or stem cell features might explain frequent relapses and the poor outcome of patients with acute myeloid leukemia (AML). LSCs are heterogeneous for their phenotypes and their sensitivity to chemotherapeutic agents in vivo. Using in silico and functional approaches, the inventors uncovered that CALCRL is overexpressed in LSCs compared with normal hematopoietic cells. They further demonstrated that the CALCRL ligand adrenomedullin (ADM) is highly expressed in AML cells and that increased transcript level was markedly associated with decreased complete

Title: *In vitro* cell-based approach to explore the regulatory activity of Adrenomedullin in AML epigenetics.

Gene Expression Datasets

Gene expression data were obtained from the BLUEPRINT consortium (http://dcc.blueprint-epigenome.eu/#/home) (24) and the Gene Expression Omnibus (GEO) repository [https://www.ncbi.nlm.nih.gov/gds, GSE98791 (25), GSE24759 (26), GSE24006 (27), GSE63270 (28), GSE158596 (29), GSE117090 (30), GSE14924 (31), GSE14468 (32), GSE6891 (33), GSE13159 (34)]. Array data from 61 AML bone marrow samples (blasts ≥80%) and 29 Philadelphia-negative (Ph−) B-ALL have been generated by the Next Generation Sequencing platform for targeted Personalized Therapy of Leukemia (NGS-PTL) project, as previously described (35, 36). The Beat AML (37) and The Cancer Genome Atlas (TCGA) project on AML (38) transcriptomic cohorts were obtained from https://portal.gdc.cancer.gov (projects BEATAML1.0-COHORT and TCGA-LAML), respectively. The datasets used in the manuscript are described in **Supplementary Table 1**.

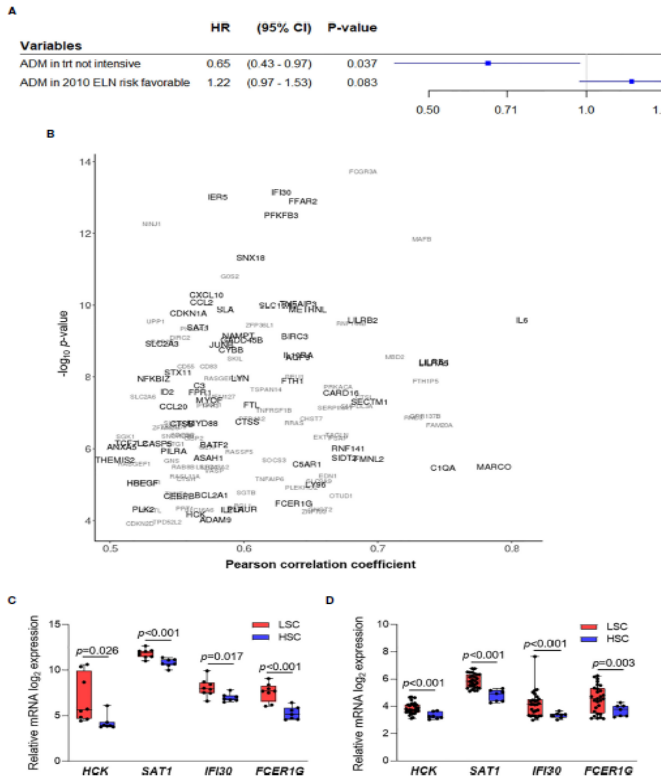

FIGURE 3 | *ADM* prognostic role and co-expressed genes in AML. **(A)** Results from two separate Cox regression models within the subgroup with 2010 ELN favorable risk (adjusting for age, n = 214) and within the subgroup receiving a not-intensive treatment (n = 64, HR, Hazard ratio, CI, confidence interval, trt, treatment). **(B)** Correlation analysis between *ADM* expression and the AML transcriptome across bone marrow samples from five AML datasets (GSE6891, GSE13159, Beat AML, TCGA-LAML, NGS-PTL). Genes showing an absolute value of Pearson correlation coefficient ≥0.50 and a *p* value ≤0.05 in at least two cohorts were reported. Genes are represented according to the weighted arithmetic mean of the correlation coefficient and *p* value across the datasets. The scatter plot was generated with the R package ggplot2 (48) (version 3.3.1). **(C)** Transcriptional analysis of *ADM* co-expressed genes in LSC compared with HSC in the GSE24006 and **(D)** in the GSE117090 datasets (fold change ≥1.5 and *p* ≤0.05 were set as cut off). The boxes extend from minimum to maximum values, each individual value is plotted and the line represents the median value.

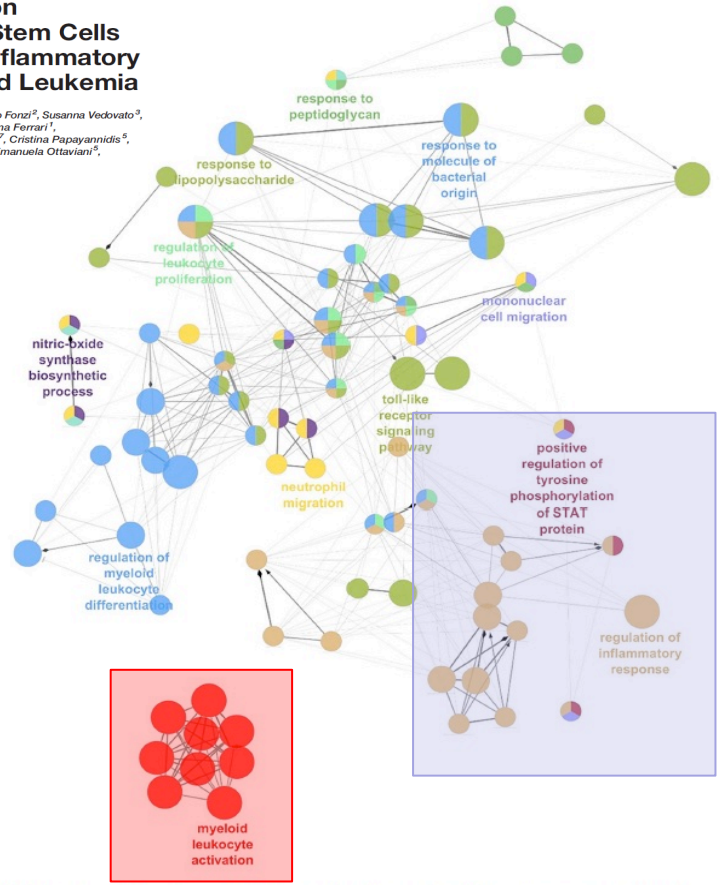

FIGURE 4 | The network of *ADM* co-expressed genes in AML. Network analysis of the Gene Ontology Biological Processes pathways enriched by *ADM* co-expressed genes in AML (ClueGO). Colors indicate functionally-related pathways; one representative pathway for each subnetwork is specified.

Role of Adrenomedullin in Leukemic Endosteal/Vascular Niches

GIMEMA AML2220

ClinicalTrials.gov Identifier NCT04460963

STUDY DESIGN

The present study will be divided into 5 phases:

1. Collection of bone marrow and peripheral blood (PB) samples from AML patients at diagnosis, at CR, at the end of treatment and at relapse;
2. Measurement of Midregional Proadrenomedullin (MR-proADM) plasma concentrations with an Immunoluminometric Assay of newly diagnosed AML patients not affected by concomitant cardiovascular disease or sepsis.
3. Analysis of exosomes and microvesicles derived from PB and bone marrow samples of AML patients and culture media collected from AML samples stimulated with ADM and/or ADM (22-52)
4. Study of adrenomedullin system in leukemic stem cells (CD44+/CD38-/CD31+/Lin-) in order to define a correlated expression of ADM and ADM receptors (RAMPs, PAM) with adhesion molecules (CD31, CD38, CD44s, CD44v6), cell cycle regulatory proteins (p21, p27) and genes or molecules involved in the hemato
CD11b, CD11c, CD66, CD14, CD
5. *In vitro* evaluation of ADM activity
endothelial migration of blasts an
endothelial cells. To do this, leuke
by using *in vitro* models of endost
