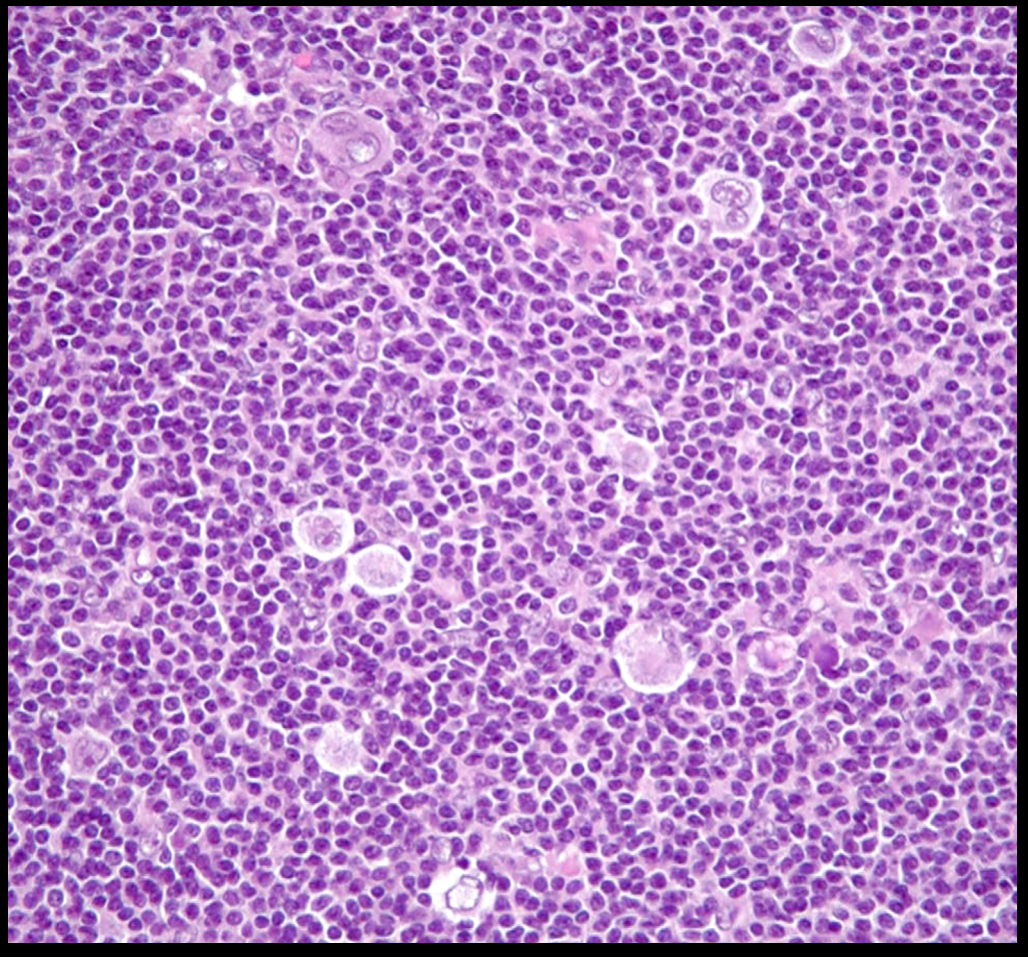
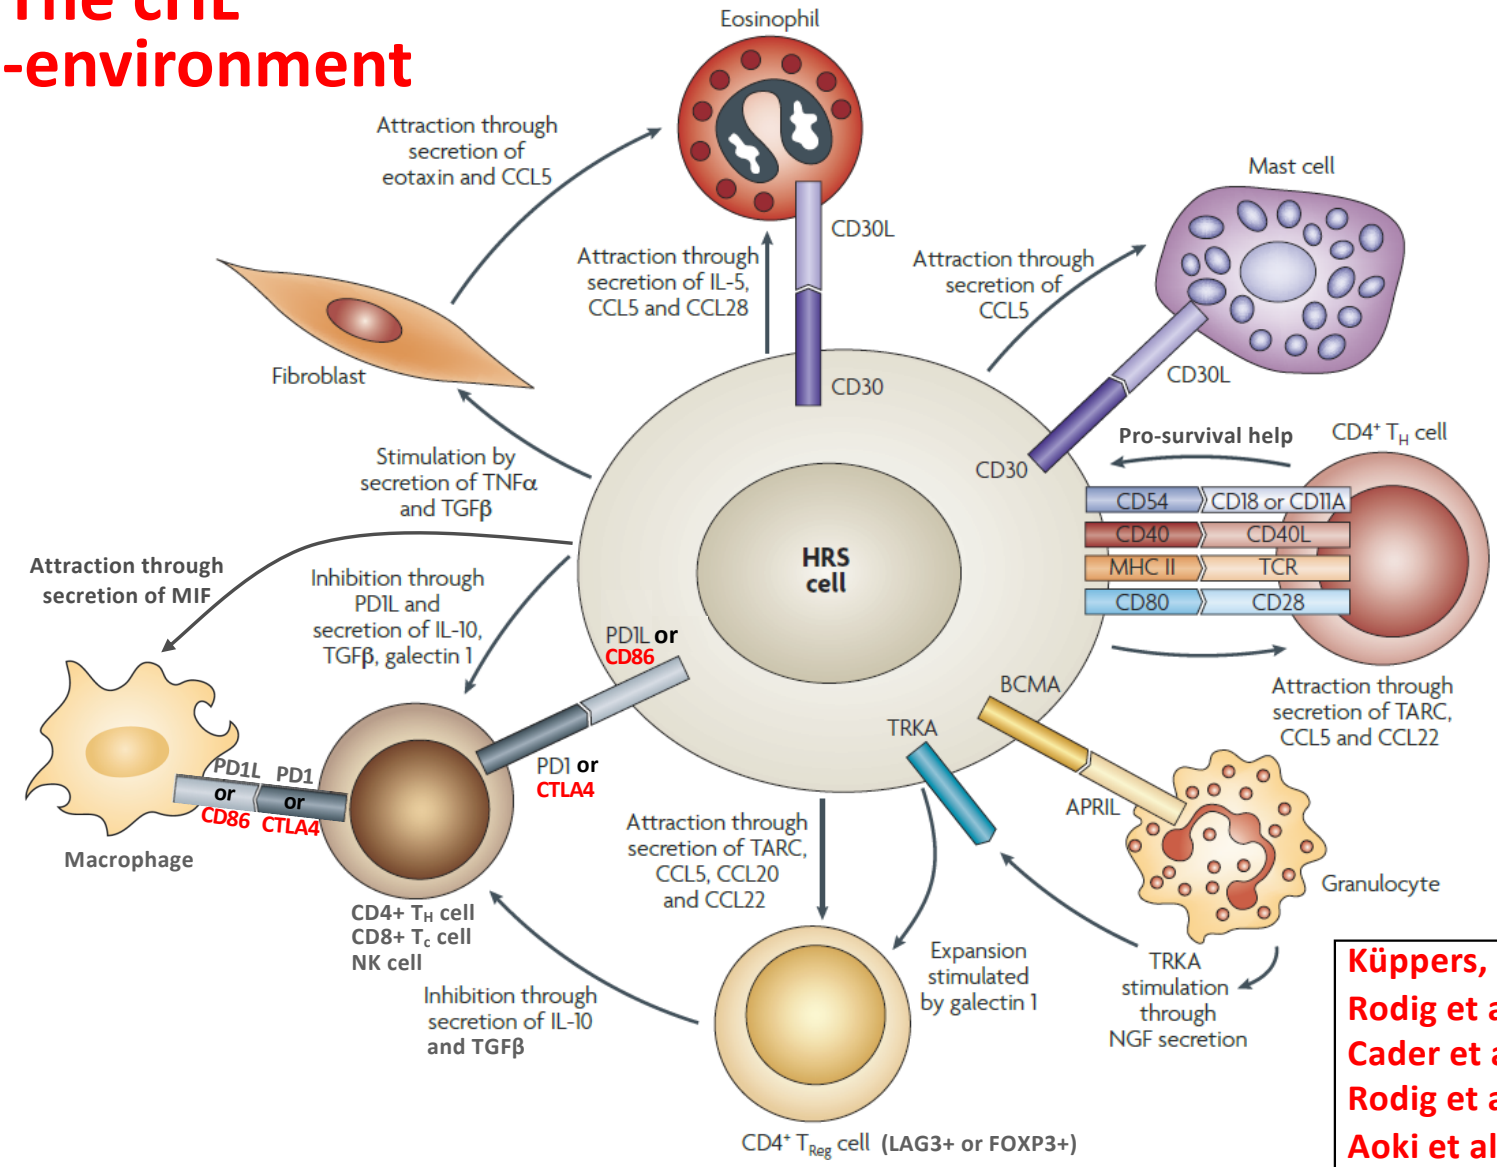
Hodgkin/Reed-Sternberg (HRS) cells

HRS cells are rare (usually <5% of lymph node cellularity) and dispersed in a prominent but immune-suppressive reactive background largely of hematopoietic origin



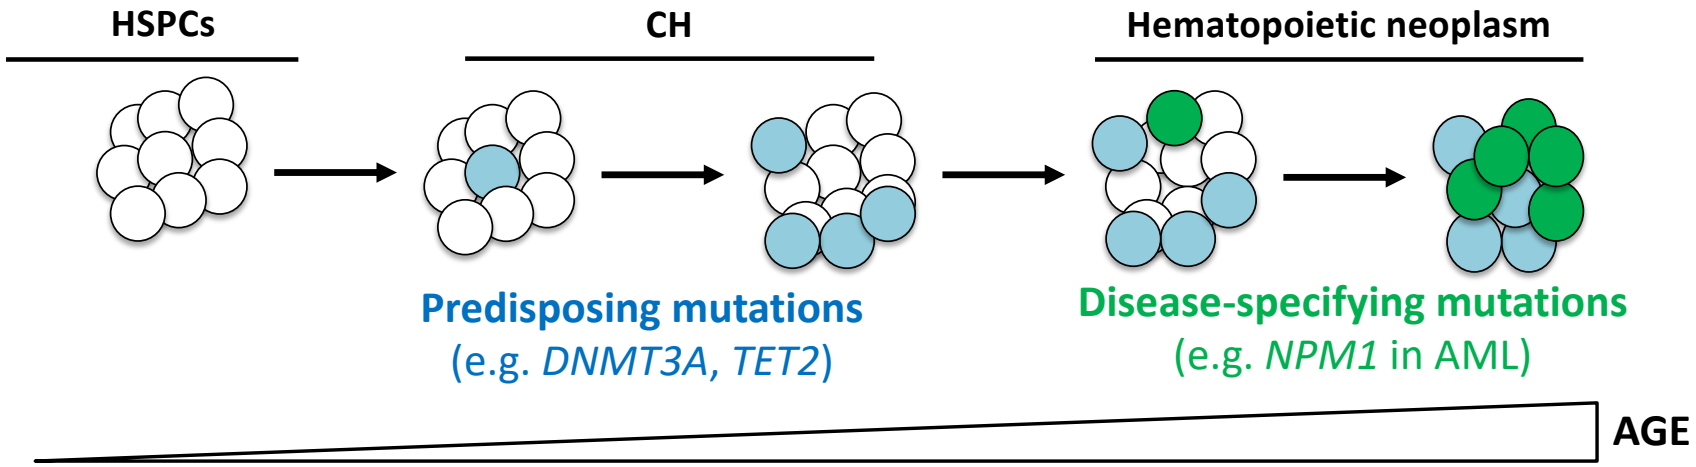
The cHL micro-environment



Küppers, Nat Rev Cancer 2009 [modif.]
Rodig et al, Blood 2017
Cader et al, Blood 2018
Rodig et al, Blood 2019
Aoki et al, Cancer Discov 20200

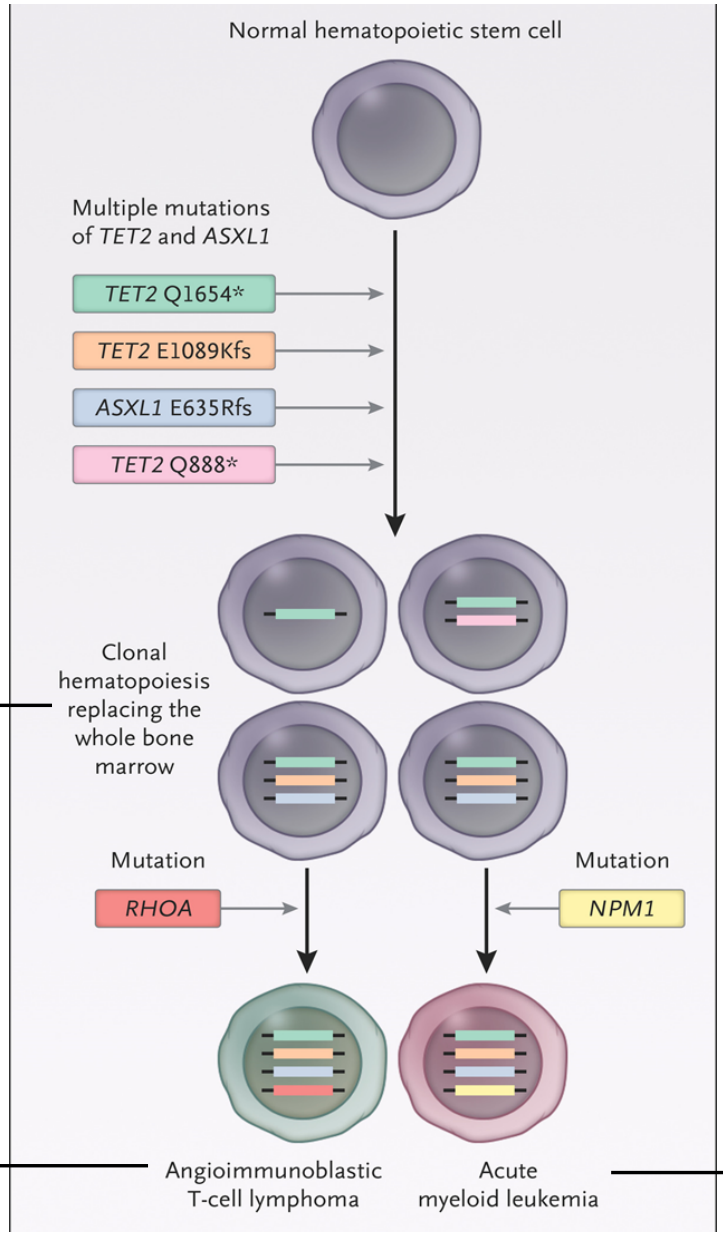
CLONAL HEMATOPOIESIS (CH)

- CH is promoted by the **age-related stochastic occurrence** in hematopoietic stem/progenitor cells (**HSPCs**) of gene **mutations conferring a fitness advantage**
- CH is **frequent in the elderly**; it **predisposes** to atheroscelosis and **to hematopoietic neoplasms mostly of myeloid or T-cell origin**
- CH with indeterminate potential (CHIP): CH with a mutant allele frequency ≥ 2% in the blood
  The **risk** of **tumor** development **depends on** the number and type of **mutated gene(s)** and on **clone size**



Quivoron et al., Cancer Cell 2011
Jaiswal et al, NEJM 2014 & 2017
Genovese et al, NEJM 2014
Tiacci et al, NEJM 2018

Tiacci et al, NEJM 2018



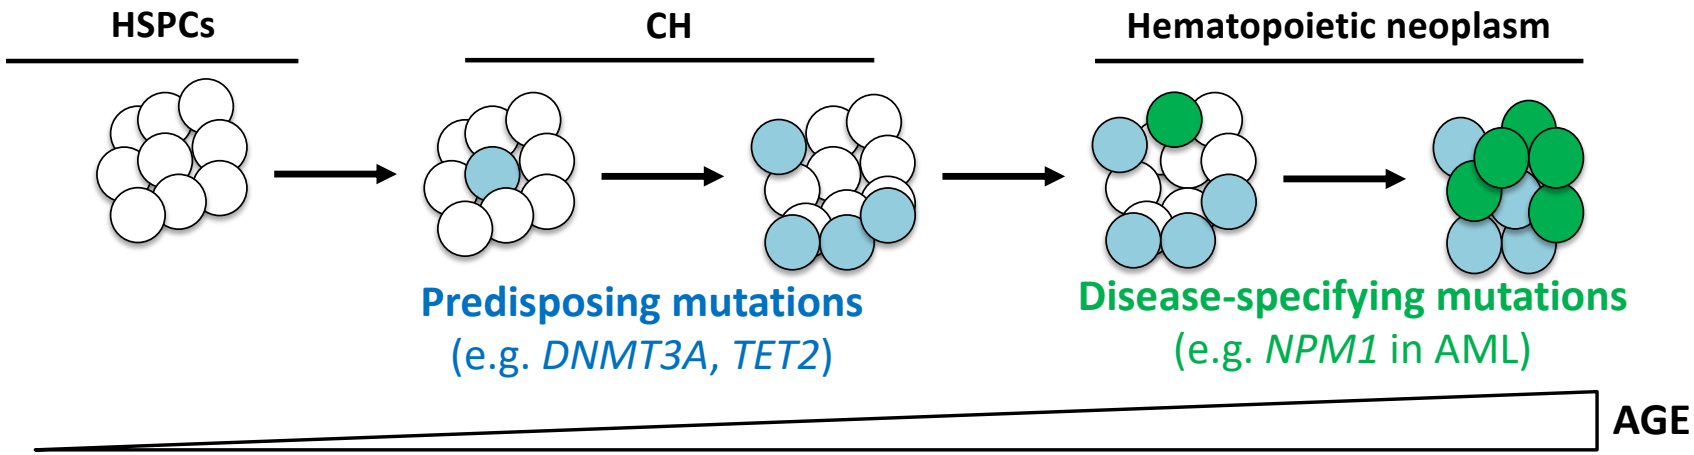
Massive CH (~90% of bone marrow cells), but normal blood counts and no dysplasia

45-year old patient
CR after CHOEP + autotransplant

1 year after lymphoma diagnosis

CLONAL HEMATOPOIESIS (CH)

- CH is promoted by the **age-related stochastic occurrence** in hematopoietic stem/progenitor cells (**HSPCs**) of gene **mutations conferring a fitness advantage**
- CH is **frequent in the elderly**; it **predisposes** to atheroscelosis and **to hematopoietic neoplasms mostly of myeloid or T-cell origin**
- CH with indeterminate potential (CHIP): CH with a mutant allele frequency ≥ 2% in the blood
  The **risk** of **tumor** development **depends on** the number and type of **mutated gene(s)** and on **clone size**



CH found in HSPCs from 9/64 (14%) relapsed cHL cases undergoing autotransplant

But: no data on the presence of **CH in the microenvironmental and/or neoplastic tissue components of cHL**, a germinal center B-cell lymphoma most frequent in the young and with the most **abundant microenvironment** (largely **hematopoietic**)

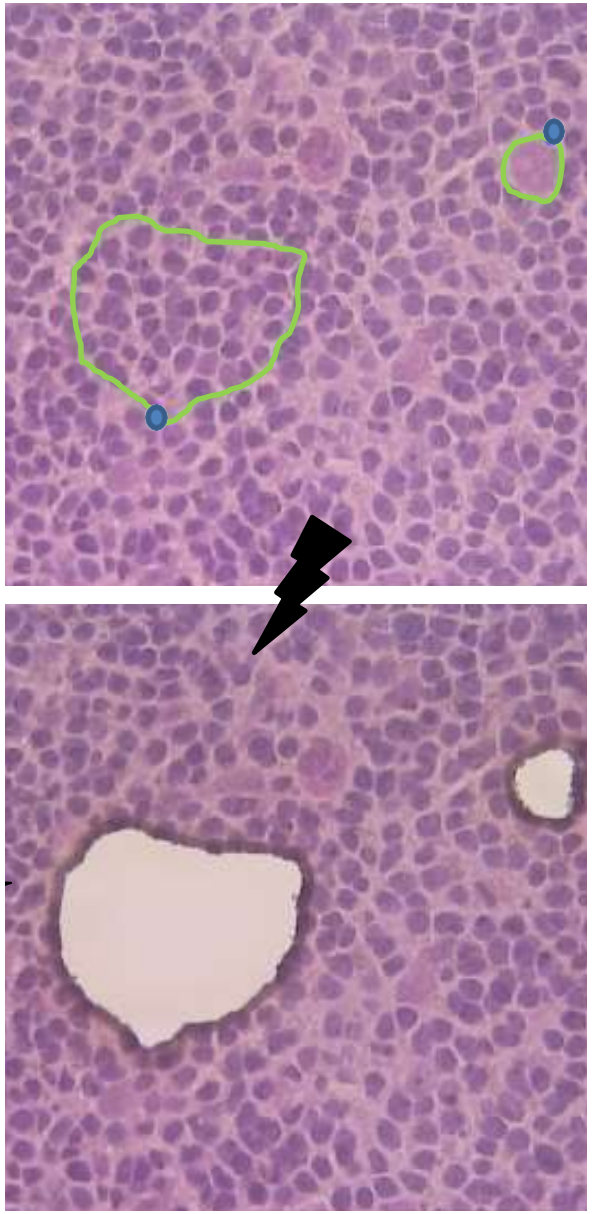
Tiacci et al, NEJM 2018
Husby et al, Leukemia 2020



Clonal hematopoiesis (CH) in cHL - AIMS AND METHODS

- Characterization of **CH frequency and tissue distribution** in **40 cHL cases,** largely studied at disease onset (n=33; at relapse, n=7)

- **Laser microdissection**, from frozen lymph node sections stained with hematoxylin and eosin, of 1200-1800 **HRS cells** and as may **reactive cells** (mostly of lymphoid morphology), followed by whole-genome amplification in duplicate

- **Whole-exome sequencing** (n=34 cases*; mean coverage ~150X) **and/or targeted sequencing** of **35 genes driving CH°** (n=9 cases; mean coverage ~3500X) on **HRS and reactive tissue cells** (n=40 cases), as well as matched **blood leukocytes** (n=27 cases)

- **CH** defined as the presence of a **mutation in a CH driver gene** at a variant allele frequency (**VAF**) **≥ 2%** in non-neoplastic blood and/or tissue cells

°As defined by Tuval & Shlush, Haematologica 2019

*From Tiacci et al., Blood 2018

Clonal hematopoiesis (CH) in cHL - RESULTS

- ***Case cohort:***
  40 patients (pts.)
  Median age: 35 years (range 15-83)
  5 pts. had >70 years
  13 pts had >55 years

- ***CH in 5/40 pts. (12.5%)***: more often in pts. >70 years (3/5, 60%) than in pts. <70 years (2/35, 6%; p<0.05)

- ***Extensive tissue CH in 3/5 pts.:***
  - aged 30-45-73 years
  - CH in up to 92%-60%-33% of reactive cells

Clonal hematopoiesis (CH) in cHL: clinico-pathological correlations

N=40 patients		CLONAL HEMATOPOIESIS IN cHL TISSUE		P-value[b]
		Extensive[a] (n=3)	Absent/non-extensive (n=37)	
AGE	>60 years	1 (33%)	9 (24%)	1
	<60 years	2 (67%)	28 (76%)	
EBV STATUS	EBV+	1 (33%)	8 (22%)	0.55
	EBV-	2 (67%)	29 (78%)	
HISTOTYPE	Nodular sclerosis	1 (33%)	21 (57%)	0.58[c]
	Mixed cellularity	2 (67%)	12 (32%)	
	Other	0 (0%)	4 (11%)	
CLINICAL STAGE	Early (≤ IIA)	1 (33%)	13 (37%)[d]	1
	Advanced (≥ IIB)	2 (67%)	22 (63%)[d]	
OUTCOME OF FIRST-LINE THERAPY[e]	No progression	0 (0%)	24 (69%)[f]	0.043
	Progression	3 (100%)	11 (31%)[f]	
	Follow-up in months[g]	0-6-35	64 (median)[g]	0.034
			0-149 (range)[g]	

Extensive clonal hematopoiesis (VAF >10%) in the cHL tissue correlated with poorer prognosis

[a] Extensive: variant allele frequency (VAF) ≥10%.
[b] By Fisher exact test, except for comparison of follow-up where T-test was used.
[c] Nodular sclerosis vs all other subtypes.
[d] Clinical stage at diagnosis was not available for two patients (UPN26; UPN40).
[e] ABVD in all cases (except COPP/ABV in pediatric patient UPN27 without clonal hematopoiesis not progressing after first-line therapy; and COPP without vincristine in elderly patient UPN41 (Case 3), whose outcome was not evaluable), with omission of bleomycin in 3/35 patients (UPN13, UPN25/Case 4, and UPN30, all without extensive clonal hematopoiesis in the cHL tissue and all not progressing after first-line therapy).
[f] Outcome was not available for one patient (UPN40) and was not evaluable in another patient (UPN41-Case 3) who died early due to acute chemotherapy toxicity.
[g] Follow-up was not available for one patient (UPN40) and not evaluable in another (UPN41-Case 3).

Venanzi, …, Tiacci Blood Cancer Discov 2021

Clonal hematopoiesis (CH) in cHL - CONCLUSIONS

- CH can be observed in cHL **(5/40 cases; 12%)** and displays **a diverse propagation pattern through the HRS-cell and microenvironmental tissue components**, with representation in both (n=1), or only in the microenvironment (n=3) or in none of them (n=1).

- **Extensive tissue CH** was present in 3/5 cases (involving up to 32%-94% of reactive cells), which **all progressed after first-line therapy** (vs 11/35 pts with absent/non-extensive CH; p-value 0.043).

- Multiple lymphoid and myeloid neoplasms in a patient with CH (even when massive) do not necessarily derive all from CH.

- CH might contribute to the **pathogenesis and prognosis of cHL**

	EXTENSIVE TISSUE CH (VAF >10%)	
PATIENTS (n=40)	**ABSENT**	**PRESENT**
Number of cases	37 (92.5%)	3 (7.5%)

Academic multi-center phase-2 trial of the oral JAK1/2 inhibitor ruxolitinib combined with either brentuximab or pembrolizumab in rel./refr. cHL patients

- JAK-STAT pathway gene mutations almost ubiquituous in cHL
- JAK2 inhibition kills cHL cell lines with mutant *STAT6* or *STAT3* *in vitro*
  Adding brentuximab to ruxolitinib eradicates their xenograft in vivo

Tiacci et al, Blood 2018
Wienand et al, Blood Adv 2019
Hao et al, CCR 2014
Lee et al, Oncotarget 2018
Ju et al, PNAS 2016

- Monotherapy with ruxolitinib is safe and has some efficacy in relapsed/refractory cHL patients

  South Korean study (BMC Cancer 2019):
  - 13 pts. with 4 median prior lines (84% refractory to last prior line)
  - 46% overall responses (1 CR, 5 PR), lasting a median of 5.6 months
  - Ruxolitinib given at 20 mg b.i.d. for a median of 20 weeks; largely grade 1-2 toxicities

  Lysa study (Haematologica 2018):
  - 33 pts. with 5 median prior lines (82% refractory to last prior line)
  - 18% best overall responses (1 CR, 5 PR), lasting a median of 7.7 months;
  - Transient disease stabilization in 33% (11/33) pts.
  - Ruxolitinib given at 20 mg b.i.d. for a median of 16 weeks; largely grade 1-2 toxicities

- Brentuximab and PD1 inhibitors effective in relapsed/refractory cHL, but CR rate still relatively low (12-34%)
- Aim: to increase the CR rate in patients eligible (and naive) to brentuximab or pembrolizumab per EMA label by combining ruxolitinib (up to 24 weeks) with brentuximab (up to 8 doses) or with pembrolizumab (up to 8 doses), respectively, in two parallel non-randomized cohorts
- Biomarkers of response (e.g., gene mutations of JAK-STAT and other pathways) in solid and liquid biopies

Academic multi-center phase-2 trial of the oral JAK1/2 inhibitor ruxolitinib combined with either brentuximab or pembrolizumab in rel./refr. cHL patients

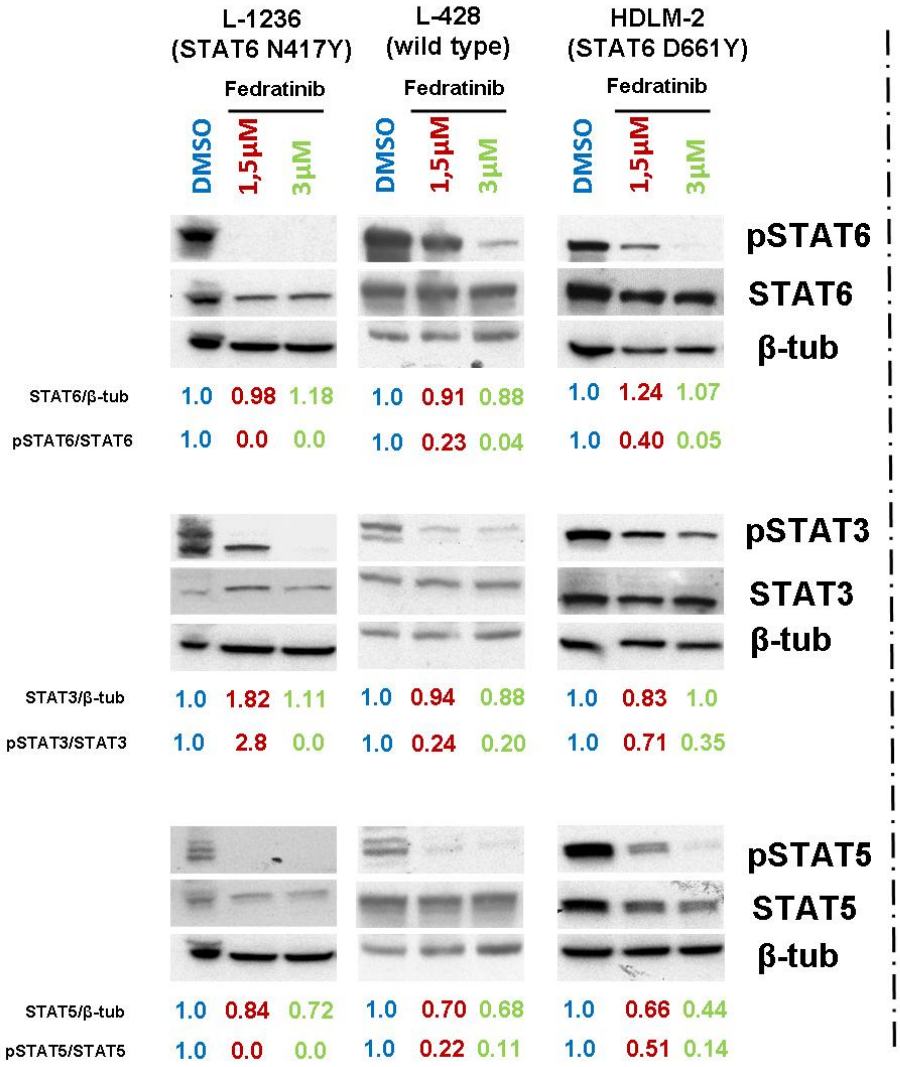
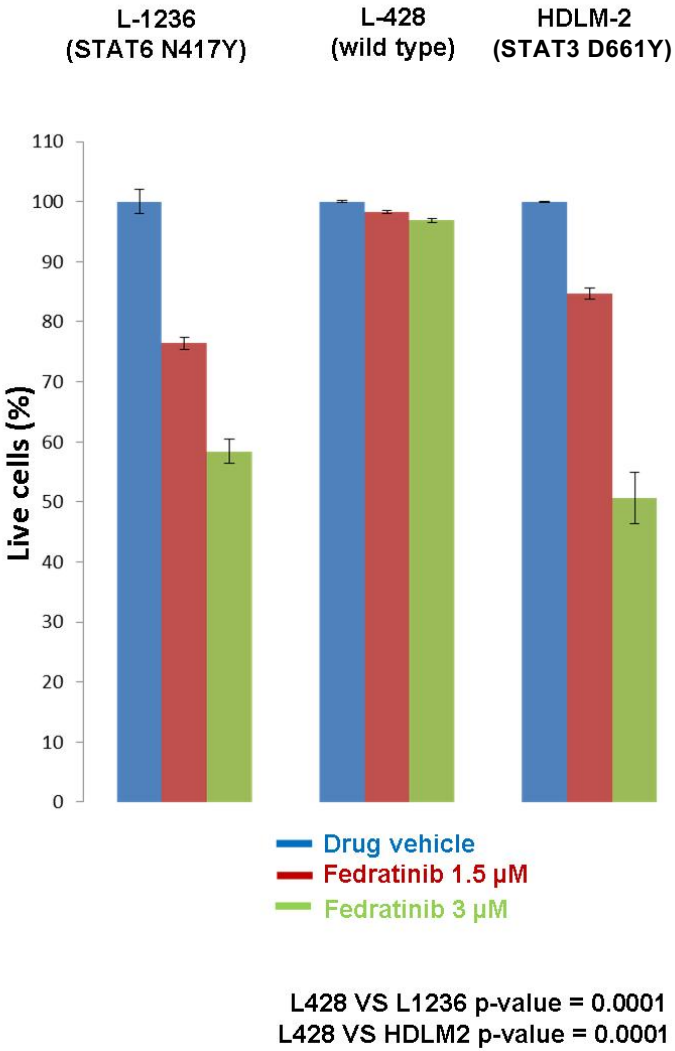
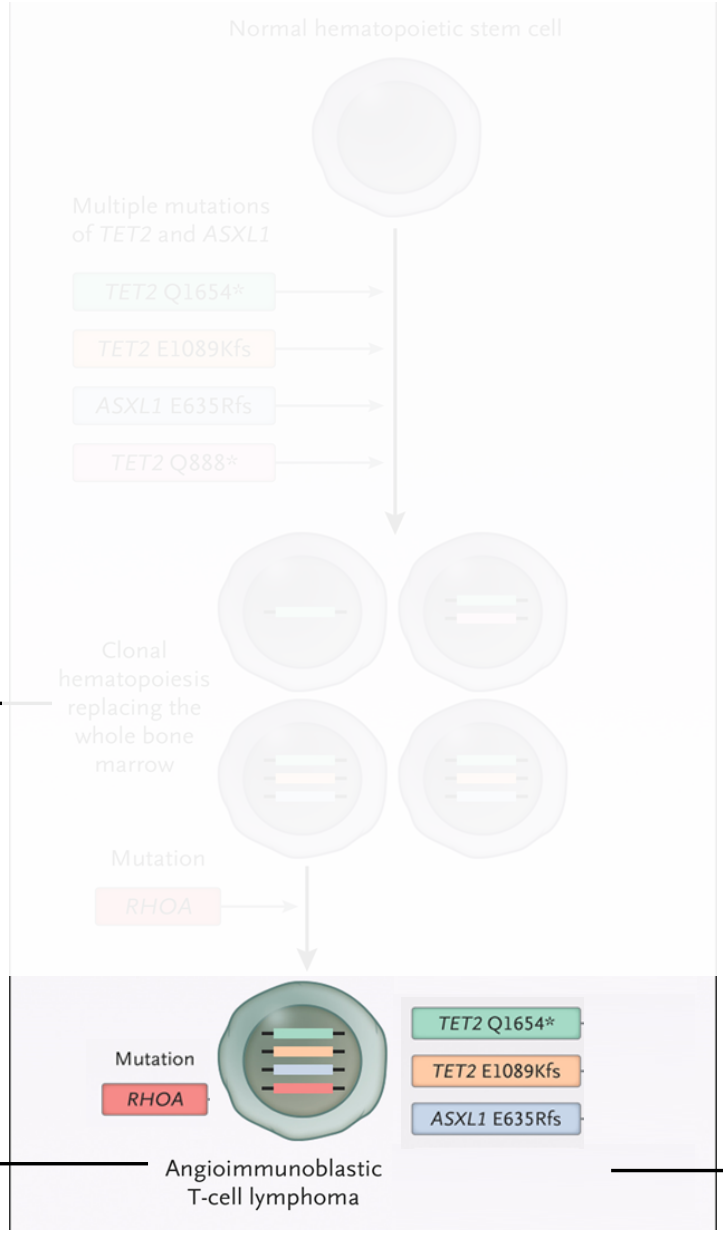
PHARMACOLOGICAL JAK2 INHIBITION CAUSES APOPTOSIS OF cHL CELLS WITH *STAT* GENE MUTATIONS





Tiacci et al, NEJM 2018



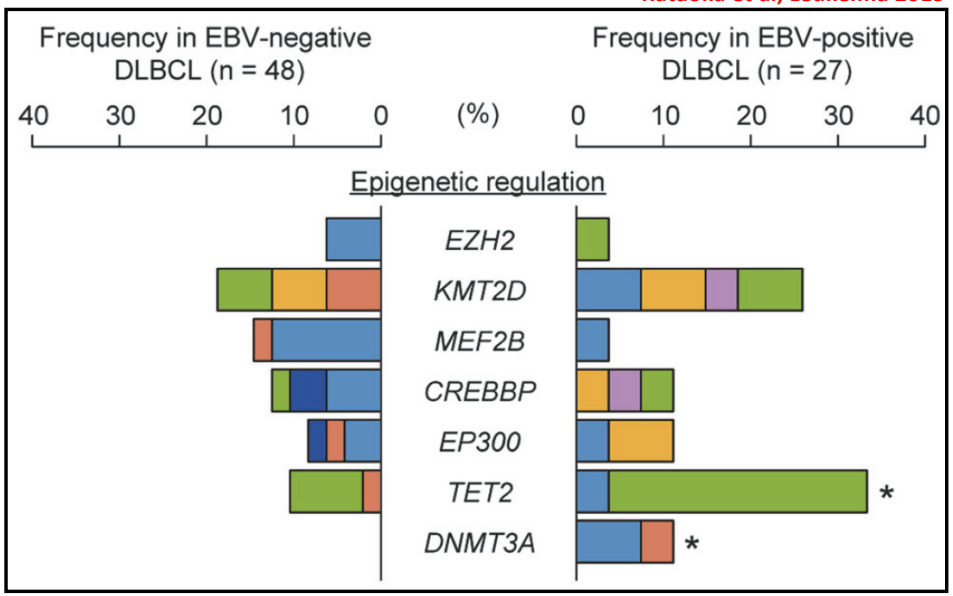
Massive CH (~90% of bone marrow cells), but normal blood counts and no dysplasia

45-year old patient
CR after CHOEP + autotransplant

1 year after lymphoma diagnosis

CASE 5
(EBV+, Mixed Cellularity)

Kataoka et al, Leukemia 2019



- First description of mutations in the epigenetic DNA modifiers *DNMT3A* and *TET2* in tumor cells of cHL[1]
- **TET2** functions as a **tumor suppressor gene in germinal centre (GC) B-cell lymphomagenesis**[2], and is **mutated in** diffuse large B-cell lymphomas (**DLBCL**) at a frequency of 10% overall[3] and 48% within the genetic subtype ST2 (largely of GC B-cell phenotype)[4]
- In **DLBCL: TET2 and DNMT3A mutations** are **more frequent in** tumor cells of **EBV+** vs EBV- cases (TET2: 33% vs 10%; DNMT3A 11% vs 0%; $p < 0.05$); and ***DNMT3A* mutations** were found **only in EBV+ cases comutated for TET2**[5]

This **genetic configuration is similar to cHL Case 5**, which featured an **EBV⁺** lymphoma cell clone carrying **DNMT3A and TET2 comutations** (in addition to an extensive clonal hematopoiesis of the tumor microenvironment)[1]

Potential role for DNMT3A and TET2 comutations in the pathogenesis of some EBV+ Hodgkin and non-Hodgkin GC B-cell derived lymphomas?

MAIN SOMATIC GENETIC LESIONS IN cHL (activating; inactivating)

OTHER GENETIC LESIONS:

- TP53 mutation (10%)
- ITPKB mutation (15%)
- TNFRSF14 deletion (20%)
- ARID1A mutation (25%)
- XPO1 mutation/gain (20%)

Schiavoni and Tiacci, EHA 2018 Educational Book (updated)

GENETICS OF CLASSICAL HODGKIN LYMPHOMA

- Landscape of frequently mutated genes in cHL largely defined
  - *NF-KB signaling*: TNFAIP3, REL, NFKBIA, NFKBIE, NIK
  - *JAK-STAT* signaling: SOCS1, JAK2, STAT6, PTPN1
  - PI3K-AKT signaling?: GNA13, ITPKB
  - Immune evasion: PDL1/2, B2M, CIITA
  - Other genes: XPO1, TP53, KMT2D/MLL2, TNFRSF14/HVEM
- Better understanding of cHL pathogenesis
- New therapeutic targets:
  - actual, i.e. PD1 inhibitors
  - potential, e.g. JAK and XPO1 inhibitors
- New liquid-biospy targets for non-invasive:
  - cHL genotyping
  - monitoring of clonal evolution
  - monitoring of response to therapy
- All cHL-mutated genes also found in other lymphomas, and likely not explaining the unique phenotype and histo-morphology of cHL:
  - particular sets of mutations must occurr in a certain order during specific GC and/or post-GC B-cell stages to produce cHL vs NHL?
  - mutations in the non-coding genome?

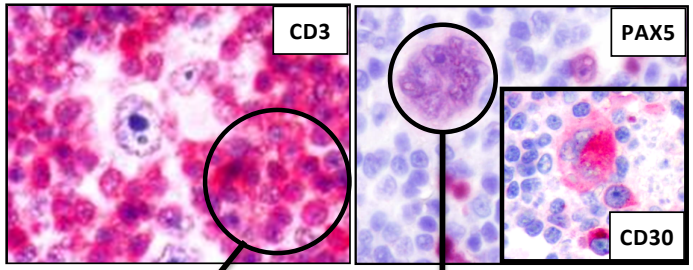
B cells: DNMT3A-R882H 48%

D

DNMT3A-R882H 7%

Classical Hodgkin Lymphoma
(lymph node biopsy)

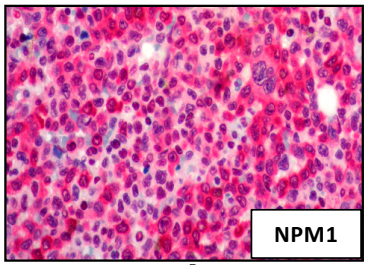


DNMT3A-R882H 16%

DNMT3A wild-type
STAT6-N417Y 37%
SOCS1-P83Afs* 99%

6 years after therapy for cHL
ABVD, IGEV, ABMT, RT

[De novo ?] Acute Myeloid Leukemia
(bone marrow biopsy)



DNMT3A-R882H 45%
NPM1-W288Cfs* 41%
Normal karyotype
TP53 and PPM1D wild-type
